LATE ADVERTISEMENTS.

GLUE.—Traveller, with experience, wishes to Represent an English manufacturer already having connection in London.—"1,432," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

PLUMBER, 27, wants work; well up in explosives factory; good references; abstainer.—"1,430," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

WANTED, Second-hand Dehne Filter Press, with thorough extraction; wood or iron; filtering surface about 200 square feet.—Full particulars to "1,431," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

WANTED, experienced man to manage small works abroad, manufacturing Fish Manure, Fish Oil, &c.; one capable of erecting and supervising plant preferred.—State age, experience, salary required, &c., to "Fish," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—
"Trepex, London."
"Expert, Manchester."

Our Telephone Numbers are:—
London: 13692, Central.
Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Readers will oblige by making their remittances or subscriptions by Postal or Post Office Order, crossed and payable to "Davis Bros."

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Readers are invited to forward items of intelligence, or cuttings from local newspapers, of interest to the trades concerned.

THE BOARD OF TRADE.

THERE can be no doubt that the problems of trade and industry are now receiving more sympathetic and practical treatment in official circles than has been the case for some considerable time. We have frequently commented in these columns on the mismanagement of great industrial questions by the Government department to which is intrusted the administration of this section of national affairs, and we have also carefully recorded the continuous and well-directed efforts of bodies, such as the Associated Chambers of Commerce, for securing the necessary measures of reform. The manufacturers and traders of the country recently received with amusement and ridicule the information—elicited during the deliberations of a Committee of the House of Commons—that the Board of Trade, as at present constituted, includes amongst its members at least one high ecclesiastical dignitary, and several other worthies equally ignorant of industrial subjects. This information, however, was tempered with the assurance that the Board of Trade never meets, and that its executive responsibilities are vested in its President. On the appointment of the new head of the Department, Mr. Lloyd-George, M.P., we ventured the criticism that since the reform of the Board of Trade was admittedly imperative, it was somewhat of an anomaly to find the office filled by a lawyer. We comforted ourselves, however, with the reflection that, given the necessary administrative ability, coupled with broad views as to the claims of commerce and industry, Mr. Lloyd-George could scarcely fail to do better than his predecessors in office. He has now had a sufficiently prolonged trial to justify some review of his achievements, and we think it will be conceded by unbiassed critics that he has emerged from the ordeal with a very fair degree of success.

One of the new President's first measures was an Act providing for a periodical industrial census, as the result of which it is hoped that we shall be placed in possession of more complete and accurate information as to the state of the trade of the country. He next secured the passing of a measure for the better regulation of the merchant shipping industry, and this without arousing antagonism from the various interests concerned. His Bill to reform the Patent Laws is so recent as not to require further recapitulation here; as to the benefits which will accrue to British trade from the working of that measure it is too early to venture an opinion.

There can be no doubt that Mr. Lloyd-George has made a very creditable attack on the arrears of commercial and industrial legislation which were left to him by his predecessors at the Board. The administration of the Department was discussed at some length in the House of Commons on Thursday of last week, when the Civil Service

80520

Digitized by Google

estimates came up for consideration. During the debate on the vote for the expenses of the Board of Trade, Sir C. McLaren said that everybody connected with trade and commerce extended their cordial congratulations to Mr. Lloyd-George on the way in which he had administered the affairs of his Department during the last eighteen months. Sir F. Channing raised the question of railway rates, and asked the President of the Board whether, in the event of the Bill dealing with the terms of owners' risk contracts passing this session, he could hold out any hopes that the question would be dealt with in the near future. In reply, Mr. Lloyd-George observed that it would be out of order for him to say anything about the subject, as there was already a Bill before the House. His views were well known, however, and he hoped that that Bill, which had passed through the Grand Committee, would become law.

Sir F. Channing also called attention to the combination of railway companies which had been initiated during the last year or two, and which culminated in a specific agreement in January last. In reply, Mr. Lloyd-George said that with regard to this arrangement, which had been entered into with a view of putting an end to the rebate system, he had expressed his views very fully to a deputation. In so far as it was an arrangement for destroying competition and preventing the reduction of rates to traders it was a bad arrangement. There were two possible systems—the present system of private enterprise in this country, and the system of State-owned railways, as in Germany, Belgium, India, and some of our colonies. Free and open competition ought to be one of the greatest advantages of the system of private enterprise, and if the public was to lose the advantages of private ownership without securing any of the advantages of public ownership, then the people of this country would have to reconsider their attitude towards the transport system. That was all he could say on the subject at present.

Sir John Brunner, M.P., who also took part in the discussion, said it was to the administration of the Board of Trade that he largely looked for benefit to the commerce of the country. He asked the President of the Board to press forward with the inquiries he was making, to enlarge them, and to inquire not only with regard to the purchase of railways, but with regard to other public works. The prosecution of this policy of public works would bring much prosperity to the manufacturers of the country. We had a higher cost of inland transit for goods than any country of the world.

In his general reply on the debate, Mr. Lloyd-George said there was no doubt that in common with one or two of the great manufacturing countries of the world we had had a very considerable boom in trade, and judging from the Board of Trade returns we had a larger proportion of the international trade of the world than almost any of our competitors. The returns for the last five months showed that while, the increase in our imports had been about a million the increase of our exports had been twenty millions. Employment was on the whole very satisfactory, and he saw no signs at present of a reaction in trade. There seemed at one time some prospect of a break-up in the German boom, but now things were looking very much better. Employment in this country was improving, and the percentage of unemployment had gone down very considerably as compared with two or three years ago. There had been a very considerable increase in wages, amounting during the five months of the year to something like five millions.

There still remains much work to be done before the reasonable demands on the Government by manufacturers and traders can be regarded as having received adequate attention, and we await with interest the further development of the programme of reform which has been outlined by the new President of the Board. The reform of the Consular service still awaits his attention, while the revivification of our canal system will afford ample scope for the most vigorous treatment. There is reason, however, to be satisfied with the progress that has been made, and we confidently anticipate the realisation of the other reforms so long demanded by those most intimately concerned with British trade and industry.

CHEMICALS IN FRANCE.

CALAIS AND DISTRICT.

MR. Consul Pagton, in his report on the trade of Calais and district for 1906, states that the principal articles of import at Calais during 1905-06 were manganese—of which 5,989 tons were imported in 1905 and 3,323 in 1906—and petroleum, both raw and heavy oils. Imports of the former averaged, from 1901-05, 13,770, and the latter 1,726 tons. Russia, U.S.A., and Belgium were the principal places of import.

The principal articles of export were chalk (average export for 1902-05 7,958 tons, U.S.A. and Norway principal export countries), chemical products (64 tons average for 1901-05, United Kingdom export country), ochres, phosphates, and carbonate of potash (all exported to United Kingdom; average of ochres increasing, of phosphates and carbonate of potash, 453 and 108 tons respectively).

The production of lime at Calais has been injured by importation from Belgium. There are two soap factories with a production of £16,000. to £20,000. yearly, half for home consumption and half for export.

BOULOGNE.

The principal imports at Boulogne during 1905-06 were:—

Chemicals ...	1,182	tons average for five years.	
China clay ..	529	,,	,,
Iron ore	26,509	,,	,,
Salt	4,451	,,	,,

Other goods came from the United Kingdom.

The principal exports for the same period amounted to:—

	1905.		1906.	
*Cement	10,279	..	9,993	tons.
*Chalk	—	..	4,669	,,
Glue	665	..	695	,,
Phosphate of Lime	4,055	..	3,404	,,

* Cement and chalk to Brazil and Argentine, U.S.A., respectively.

LILLE.

The year's production of alcohol from beet was 24,276,000 gallons, being greatly in excess of 1905. The price of alcohol stood firm at 1s. 5d. a gallon. It is expected that the present season of production will be much the same. From molasses the 1905-06 production was 17 million gallons; the present season will probably not exceed 11 millions. The use of "denatured" alcohol for industrial purposes increases. The consumption for 1906 will be probably over 11 million gallons. Starch is prosperous, low prices of maize and rice compensating for increased cost of coal.

High prices of iron, lead, copper, phosphates, pyrites, coal, etc., were the inevitable cause of a considerable rise in chemical products. The extraordinary consumption of superphosphates caused an enormous demand for phosphates and pyrites, the latter for the production of sulphuric acid used in the manufacture of superphosphates. As the natural beds of phosphates are becoming exhausted, the price of this article rose 30 to 40% and of pyrites 10 to 15%. It is feared that the high prices of superphosphates and sulphate of copper will reduce the use of these manures, which are becoming too dear for agriculturists. In spite of the campaign against the use of white lead in paints this article maintains its position, though its prosperity is not commensurate with the present general activity in trade.

Digitized by Google

The following table shows the importation and exportation of white lead, oxide of zinc, and substitutes during the last three years :—

Articles.	1904. Tons.	1905. Tons.	1906. Tons.
White Lead :—			
Imports	2,154	2,170	1,952
Exports	2,384	3,120	3,370
Oxide of Zinc :—			
Imports	2,867	4,290	4,174
Exports	2,535	2,689	2,240
Substitutes :—			
Imports	2,823	3,601	4,412
Exports	675	482	324

This tends to show that the only effect of the campaign against white lead was an increase in the importation of substitutes, principally German lithopone.

The sugar crisis of the past year, though somewhat diminished, is still intense, as the world's production of sugar is in excess of the consumption. The general stock is much the same as in the previous year, 3,225,000 tons on December 1, 1906, against 3,330,600 tons at same date of 1905. The position of the French stock is similar, 796,000 tons December, 1906, against 734,000 tons in 1905. The difference is slight, considering that the French production of sugar during the 1906 season was, owing to short supply of sugar beetroot, too cheap to be remunerative to cultivators, who preferred to grow it for distilling purposes, only 585,000 tons, over 300,000 tons less than in 1905.

AMIENS.

Mr. Vice-Consul Sutcliffe reports that phosphates for agricultural purposes were estimated at £220,000., a great deal being exported. The distilleries produced 3,520,000 gallons of alcohol.

Land under cultivation for sugar beetroot was, for 1905-06, 682,537 acres against 503,316 acres the previous season, and the production amounted to about 12¼ tons per acre. The total crop was 8,415,807 tons, nearly double that of 1903-04. The average price paid to growers in 1905-06 per ton was 19s. 6d., against 17s. 7d. in the previous year.

There were 292 factories working, showing an increase of 22. These factories produced 984,671 tons of refined sugar. Pulps, total weight 3,799,321 tons, were re-sold at 3s. 2½d. The average density of juice was 5.62°, against 5.44° the previous year.

AMERICAN TRADE IN 1906.

IN his report on the trade and commerce of the States of Oregon, Washington, and Idaho for the year 1906, Mr. Consul Laidlaw states that the trade of the district has been in a most flourishing condition throughout the year. In the staples of wheat, flour, and timber, the exports were £834,000. more than in 1905, and imports were fully £777,000. in excess of that year. There was a good return from fisheries, and a development of mining and industrial enterprises; agricultural conditions were also favourable. The building trade has been active, and the population of all towns has increased steadily.

Cement has increased in import, and British manufacturers have endeavoured at last to recover their lost trade. From California 30,000 casks were received, an amount which would, but for the earthquake, have been exceeded. In the districts of Bellingham and Baker River there are prospects of factories being started in the near future. Early in the year consumers had to pay 12s. to 14s. a cask, but, later, cargo lots were sold at from 10s. to 11s.

Four beet-sugar factories were operated in Idaho, with a capacity of 2,650 tons daily, one in Washington of 500 tons, and one in Oregon of 350 tons. During the season they produced 72,648,000 lbs. of sugar; other mills will be open in 1907. The factories have great difficulty in getting the farmers to cultivate beets, as it is a business involving more labour than most branches of agriculture.

A continued development in mining has taken place in this district, but as there is no mining bureau in either Oregon or Washington it is difficult to arrive at figures of production, and many properties heralded as mines are merely prospects. According to the United States Geological Survey there are 1,211 mines in the State of Oregon under development, mostly gold, silver and copper, and there are said to be about 3,370 persons engaged in mining.

Cobalt has been found in quantity in Grant County, Oregon, and is being sent to Germany and to electrical works in the Eastern States. The United States Geological Survey have continued experiments with the black sand found in great profusion on this coast, and claim to have demonstrated that platinum in paying quantities, besides other valuable minerals, can be extracted readily from these sands.

The total number of fatal accidents to miners in Idaho was 17, and the number of miners employed in all the mines of that State is given as approximately 7,000.

The following table of the output of gold and silver is made up from the preliminary estimates of the United States Mint :—

State	Gold.		Silver.	
	Quantity.	Value.	Quantity.	Commercial Value.
	Fine ozs.	£	Fine ozs.	£
Idaho	58,762	242,923	9,136,800	1,214,289
Oregon	66,226	273,980	100,100	13,293
Washington	17,058	70,520	140,500	18,658
Total.....	142,046	587,423	9,377,460	1,246,240
,, 1905..	142,221	587,970	8,823,766	1,063,284

The product of the Tacoma smelting and refining works in the precious metals during 1906 is reported as follows :—Gold, 238,326.72 ozs., value £985,243. ; silver, 2,312,704.31 ozs., value £307,071. ; a decrease in gold but an increase in silver. A large proportion of the ores smelted came from British Columbia and Alaska.

Copper has been in great demand, and the average value appears to have been about 9½d. per lb. The deposits in Oregon and Washington have not been largely developed, and those of Washington County, Idaho, which are of great volume, are handicapped by want of railways, which are, however, being pushed in that direction.

The following table illustrates the increasing product of the district (only a trifle of the Idaho copper is smelted within the State, and the amount given is metal contents) :—

	1906.	1905.	1904.	1903.
	Lbs.	Lbs.	Lbs.	Lbs.
Idaho.....	11,640,565	6,661,440	5,422,007	2,524,000
Tacoma smelter.	20,121,979	20,351,261	16,125,774	10,889,463
Total	31,762,544	27,012,701	21,547,781	13,413,463

Some of the large Idaho mines which were not worked in 1905 were re-opened in 1906. The following is the output of this metal during the last two years :—

	1906.	1905.
Idaho (metal contents) ...	255,966,083	260,791,456
Tacoma smelter	30,646,381	30,032,718
Total	286,612,464	290,824,174

In 1903 the combined product was 236,740,746 lbs. ; the average market value appears to have been £1. 2s. 8d. per 100 lbs. Ores of zinc were not valued some years ago, and galena mines were sometimes closed on account of its presence in the ores. In 1906 the metal content of zinc from Idaho mines was 1,477,000 lbs., of an average value of £1. 4s. 9d. per 100 lbs. Some mines in Shoshone County, Idaho, produce high grade antimony ores, averaging 55 % of the metal. Several truckloads were sent out.

The U.S. engineers have started work on a canal round the rapids of the Columbia River, between the Dalles and Cehilo Falls. This canal will be 8½ miles long, 65 feet wide, and 8 feet deep. The locks will be 300 feet long and 45 feet wide in the clear. The cost will be £825,000., of which, up to June 30, £43,020. has been expended.

PROPOSED INTERNATIONAL EXHIBITION IN MANCHESTER.—The question is being discussed in Manchester as to the desirability of holding an International Exhibition, on the lines successfully adopted in 1887, when a surplus was realised of £50,000. A deputation of traders waited on the Lord Mayor on Tuesday last to submit a resolution in favour of organising such an exhibition.

Digitized by Google

Parliamentary Jottings.

HOUSE OF LORDS.

On Tuesday last, the Limited Partnerships Bill, which has already been passed by the House of Commons, was read a second time.

HOUSE OF COMMONS.

CORDITE.

On the 27th ult., Mr. Bellairs asked the Secretary to the Admiralty what was the date of the first sitting of Lord Rayleigh's Cordite Committee; and what proportion of the estimated £200,000. to be spent this year on refrigerating machinery for the magazines was for the ships already built, which had been officially stated to number 51 battleships, 28 armoured cruisers, and 76 unarmoured cruisers.

Mr. Lambert.—The date asked for was April 4, 1907. Of the total of £200,000., £165,700. is the estimated sum required for ships already built.

Mr. Bellairs.—Can the hon. member tell the House what was the first date on which the Admiralty received information that Kynochs were adding mercuric chloride?

Mr. Lambert was understood to reply that he could not bear the date in mind.

Mr. Bellairs.—Is the hon. member aware that the discovery was made in December, and this Committee was only appointed in April?

Mr. Lambert.—If the hon. member knows that, why does he ask me for the information?

Mr. Bellairs asked the Secretary of State for the Home Department, on what date was the discovery made of the presence of mercuric chloride in the cordite at Kynoch's magazine, near Cardiff, resulting in the seizure of 23,000lb., and whether he could state when the appeal trial of Kynoch, Limited, in reference to the addition of mercuric chloride to some blasting gelatine, was likely to be heard.

Mr. Gladstone.—The 23,000lb. of explosives which were seized at Mwyndwy Bach Farm, Glamorganshire, in December, 1906, was not cordite, but exclusively blasting explosives. The firm were suspected of using a masking agent in the summer of 1906, but it was not until just before the seizure that the inspectors were in a position to prove the presence of mercury in blasting explosives. The case which Quarter Sessions agreed to state on April 24 has only been drafted by the appellants within the last few days. This delay on their part makes it most unlikely that the case will be heard until after the vacation.

THE HOME OFFICE AND MESSRS. KYNOCH, LIMITED.

In the debate on the vote for the Home Office, Mr. Mooney, who had given notice of his intention to move a reduction of £1,000. in order to call attention to the action of the Home Office in regard to Messrs. Kynoch's factory at Arklow, Ireland, explained that he did not intend to proceed with the amendment. He was glad to say that, largely owing to the tact and courtesy of the Home Secretary, an amicable arrangement had been come to which was quite satisfactory from the Irish point of view, while at the same time it safeguarded the public interest. Mr. Gladstone had entirely removed the impression that his Department was attempting to make a distinction between English and Irish factories.

Mr. Gladstone repudiated any feelings of hostility against Messrs. Kynoch or against Irish interests. He had simply done his best to perform a difficult public duty. As this was a very important matter, it was desirable that the terms of agreement should be made public. Messrs. Kynoch had agreed to withdraw their appeal to the High Court and to accept the decision of the Essex Sessions, to write a letter to the Chief Inspector of Explosives undertaking not to use mercuric chloride or any ingredient which had a masking effect on the Abel heat test, and generally to observe the terms of their licence. They would also indicate to the Home Office the explosives now under seizure which contained mercuric chloride and hand them over to the inspectors. So far as the Home Office was concerned, it agreed that the cases pending against Messrs. Kynoch should be withdrawn, that all explosives not containing mercuric chloride should be released, and that the magazines required by Messrs. Kynoch for trade purposes should be cleared of their present contents—the explosives seized under the Act—which would be concentrated in such places as might be approved by the Chief Inspector. He thought this settlement was in the public interest and to the advantage of everybody concerned.

PATENTS AND DESIGNS BILL.

The London correspondent of the *Birmingham Daily Post* states that when the report stage of the Patents and Designs Bill introduced by the President of the Board of Trade is taken in the House of Commons, Mr. E. C. Meysey-Thompson, the Unionist member for the Handsworth Division, will move the following new clause:—

(1.) A patentee may, after advertising in manner directed by any rules made under this section his intention to do so, present a petition to the Controller of the Patent Office, praying that his patent may be extended for a further term, but such petition must be presented at least six months before the time limited for the expiration of the patent.

(2.) Any person may enter a caveat addressed to the Controller of the Patent Office against extension.

(3.) If the Controller of the Patent Office shall be pleased to refer any such petition to the President of the Board of Trade, the said President shall proceed to consider the same, and the petitioner, and any person who has entered a caveat, shall be entitled to be heard himself or by counsel on the petition.

(4.) The Controller of the Patent Office shall, in considering his decision, have regard to the nature and merits of the invention in relation to the public, to the profits made by the patentee of such, and to all the circumstances of the case.

(5.) If the Controller of the Patent Office report favourably upon the application, it shall be lawful for the President of the Board of Trade to grant an extension for a period not exceeding seven, or in exceptional cases fourteen years, or to order the grant of a new patent for the term therein mentioned, and containing any restrictions, conditions, and provisions that the Controller may think fit.

(6.) It shall be lawful for the President of the Board of Trade to make from time to time rules of procedure and practice for regulating proceedings on such petitions, and subject thereto such proceedings shall be regulated according to the existing procedure and practice in patent matters.

(7.) The costs of all parties of and incident to such proceedings shall be, in the discretion of the Controller of the Patent Office, subject to review by the President of the Board of Trade, and the orders of the Controller respecting costs shall be enforceable as if they were orders of a division of the High Court of Justice.

Reports of Companies.

KYNOCH, LIMITED.

The annual meeting of Kynoch (Limited) was held at Birmingham on the 25th ult. A net profit of £72,656. was reported, and dividends were recommended at the rate of 5% on the preference shares, and 10% on the ordinary shares.

The Chairman (Mr. Arthur Chamberlain) said the falling off in the Government orders last year was sudden, complete and absolute. Not only did the amount of Government business seriously decline, but owing to consequent keenness of the competition the profit disappeared. To meet the situation they had given more attention to the advancement of their peaceful industries. Of these they had ten under their control. The attempt to monopolise the sale of soap last year gave them a great lift, of which they took full advantage. The firm's loss by reason of the high price of metals was serious, amounting to £26,000. The dispute with the Home Office was still unsettled. It concerned the use by them of an infinitesimal quantity of mercuric chloride in the manufacture of cordite and other high explosives. That was similar to antiseptics in surgery, and had the effect of preventing bacteriological action which might arise under conditions of great heat or damp. The Home Office had seized a number of their magazines with their contents, and had held them for nine months, thus dislocating their trade, increasing their expenses through keeping a quantity of stock idle and unproductive, and giving advantage to trade rivals in Scotland and England. They were prepared to prove that the treatment with mercuric chloride always made explosives safer. The fact that the Government refused arbitration was a proof that they had no case. Kynochs had been at a disadvantage for many years past. If they were not allowed to secure the stability of their explosives when crossing the ocean by taking the necessary precautions, they were prepared to meet the case by sending their factories across the ocean and manufacturing in the markets in which they were sold—a position that would certainly not reduce their profits. The report was adopted.

THE INDIAN OILSEEDS CROP.

THE Final General Memorandum on the spring oilseeds crop of the season of 1906-7 has been issued by the Commercial Intelligence Department at Calcutta, dated May 30th.

The areas dealt with in the reports summarised below comprise, besides certain native territories, such a proportion of the respective crop areas in British India as amounts to 99.39% of the total in the case of rape and mustard, and 95.8% in the case of linseed.

In the case of rape and mustard the total area under the unmixed crop is returned as 4,196,500 acres, as against 4,052,800 acres in 1905-06, the increase being 143,700 acres or 3.5%. The total area under the "mixed" crop (that is to say, interspersed with other crops) is estimated as 2,210,000 acres, as against 2,026,000 acres in 1905-06, the increase being 184,000 acres, or 9.1%.

The total out-turn (mixed and unmixed) is computed at 1,073,600 tons, as compared with 968,700 tons in the previous year, the increase being 104,900 tons, or 10.8%.

In linseed (pure) the total area is returned as 3,028,200 acres, as against 2,711,800 acres in 1905-06, the increase being 316,400 acres, or 11.7%. The total area under the "mixed" crop is estimated as 633,000 acres, as against 567,000 acres in 1905-06, the increase in this case being 66,000 acres, or 11.6%.

The total out-turn (mixed and unmixed) is computed at 422,300 tons, as against 352,900 tons in the previous year, the increase being 69,400 tons, or 19.6%.

The following is a summary of the provincial reports. The figures in brackets, following the name of each province, indicate what percentage of the total area under the crop in British India is ordinarily cultivated in that province:—

Rape and Mustard.

United Provinces (38.5%).—The area under the *unmixed* crop is reported to be 153,400 acres, as compared with 154,700 acres last year, a decrease of 0.8%. Moisture for sowing was insufficient in the eastern submontane districts, where rapeseed is largely grown. The winter rains were late. When they arrived in February they did some good, but continued wet and cloudy weather in February and March produced fungoid disease in the greater part of the province. The injury has not, however, been so great as in the case of wheat. The out-turn is estimated at 30,000 tons, the same as in the preceding year. The area of rapeseed grown, in combination with other crops (chiefly for home consumption), is estimated at 2,210,000 acres, and the out-turn 424,000 tons, compared with 2,026,000 acres and 398,000 tons respectively for last year. These estimates are highly conjectural.

Bengal (13.4%) reports the area sown to be 818,100 acres, compared with 767,200 acres last year—an increase of 6.6%. On the whole the season was not very favourable. The out-turn is estimated at 138,800 tons, as against 118,400 tons last year—an increase of 17%.

Eastern Bengal (21.2%).—The final report has not yet been received. In February last the area was estimated to be 1,207,600 acres, compared with 1,144,500 acres for last year—an increase of 5.6%. The out-turn was estimated at 83% of normal. On this basis the gross yield amounts to 220,000 tons,* compared with 176,000 tons for the preceding year—an increase of 25%.

Assam (4%) reported 171,100 acres in March last, as compared with 164,400 acres at that date last year. The out-turn was reported to be 32,000 tons, as against 30,200 tons last year—an increase of 6%.

Panjab (18.9%) reports the area sown to be 1,471,200 acres, compared with 1,614,200 acres last year—a decrease of about 9%. The area is, however, nearly 40% larger than the average of the preceding five years. Opportune rains in the autumn were succeeded by satisfactory winter falls; but in the spring the conditions became abnormal, and excessive rains continuing through February, March and April have damaged the unirrigated crop. The out-turn is estimated at 183,300 tons, compared with 183,000 tons last year.

North-West Frontier (1.9%) reports 218,800 acres, as against 85,500 acres last year—an increase of 156%. The winter rains were copious and general. The heavy and well distributed rains from January to March were also beneficial. The out-turn is estimated to be 19,400 tons, compared with 12,200 tons last year—an increase of 59%.

The British districts of *Bombay* (0.05%) report 2,700 acres, compared with 900 acres last year. The Native States report 58,700 acres, as against 42,900—an increase of about 37%. Sowing rains were favourable, and the crop has progressed well. The out-turn is estimated to be 500 tons in British districts, and 13,600 in Native States, as against 200 and 9,100 tons respectively in the preceding year.

Sind (1.4%) reports 84,200 acres (4,200 in Native States), as compared with 64,200 acres (3,800 in Native States) for last year—an increase of 31%, attributed to favourable inundation. The crop is reported to be in a fair condition except in Larkana, where it has been damaged by rain and hail. The out-turn is estimated to be 11,800 tons (700 in Native States), as against 11,500 tons (600 in Native States) last year.

Hyderabad reports 10,700 acres and 200 tons, as compared with 14,300 acres and 100 tons last year.

Linseed.

United Provinces (35.2%).—The area under the *unmixed* crop is reported to be 315,000 acres, as compared with 210,900 acres last year—an increase of 49%. In Bundelkhand, where linseed is chiefly grown, moisture for sowing was sufficient. The winter rains were late, and when they arrived, in February, they did some good, but continued wet and cloudy weather in February and March produced fungoid disease. In Bundelkhand and Mirzapur, however, the crop escaped injury, and the yield has been good. The out-turn is estimated at 56,300 tons, as against 32,800 tons last year—an increase of about 72%. The area of linseed grown in combination with other crops (chiefly for home consumption) is estimated to be 633,000 acres, and the out-turn 113,000 tons, compared with 567,000 acres and 88,000 tons respectively for last year. These estimates are highly conjectural.

Bengal (22.7%) reports the area sown to be 671,800 acres, compared with 726,500 acres—a decrease of 7.5%. The crop suffered in Lower Bengal from excessive rain at the time of sowing, and from absence of rain in Bihar at the period of early growth. Rain and hailstorms also damaged the crop in places towards the harvesting time. The out-turn is estimated at 94,800 tons, compared with 110,500 tons last year—a decrease of 14%.

Eastern Bengal (3.6%).—The final report has not yet been received. In February last the area was estimated to be 87,700 acres, as against 103,000 acres for last year—a decrease of 15%. The out-turn was estimated at 78% of normal. On this basis the gross yield comes to 15,000 tons,† compared with 17,000 tons for the preceding year—a decrease of 11.8%.

Central Provinces and Berar (25.3%).—The total area sown is reported to be 1,145,200 acres (1,051,700 in the Central Provinces and 93,500 in Berar), compared with 912,100 acres (815,400 in the Central Provinces and 96,700 in Berar) last year—this representing an increase of 25.6%. The prolonged cloudy weather, frost, rains, and hail caused serious damage to the crop. The total out-turn is estimated to be 104,700 tons (96,000 in the Central Provinces and 8,700 in Berar), as against 77,300 tons (69,600 in the Central Provinces and 7,700 in Berar)—an increase of 35%.

The British districts of *Bombay* (9%) report 130,500 acres, compared with 139,600 acres last year—a decrease of 6.5%. The Native States report 13,700 acres, as against 15,200 acres last year—a decrease of about 10%. In East Khandesh and Satara, the crop has yielded fairly, but elsewhere in the Deccan it has suffered from want of moisture. In the Karnatak the condition of the crop is reported to be fair, except in parts of Bijapur and Dharwar, where the December rain proved injurious. The out-turn is estimated to be 5,500 tons in British districts, and 400 in Native States, as compared with 2,400 and 200 tons respectively in the preceding year.

Hyderabad reports 664,300 acres, as compared with 604,500 acres last year—an increase of about 10%. The crop is reported to be in good condition. The out-turn is estimated to be 32,600 tons, compared with 24,700 tons last year—an increase of 32%.

WARNING TO BRITISH TRADERS.—Information has been received at the Commercial Intelligence Branch of the Board of Trade relating to certain foreigners in Smyrna, formerly exporters, which will be communicated in confidence to British traders who may apply personally at 73, Basinghall-street, London, E.C.

* Report just received gives 218,300 tons against 168,100 for last year.

† Report just received gives 12,600 tons against 17,300 for last year.

Continental Notes.

In the *Chemische Industrie*, for May 15, some extracts are given from the report of the Prussian factory inspectors. Many details are cited as to the precautions that are being taken against lead poisoning and other special diseases. The men engaged in certain of the more injurious operations in lead works, for instance, are required to put on clean clothes daily instead of weekly, as was formerly the case. An interesting observation was made at an ether factory. The emptying cock of a large reservoir for ether was connected with a rubber tube, in the middle of which there was a glass tube. The lower end of the tube was introduced into the drum that was to be filled. The workman who had had charge of the operation of filling the drums for a long time had observed frequently that sparks 10 to 20cm. sprang from the glass tube to the iron drum, but he never mentioned the fact until other fire precautions were being laid down by the inspector. It was evident that electricity was generated by the friction of the ether with the glass. Although the sparks only appeared in dry weather, it was found by the manager of the works that even in wet weather considerable charges could be detected with the electroscope. Since the glass tube has been replaced by an iron one the phenomenon has ceased. Against the danger of poisoning by nitrous fumes the precaution of drinking chloroform water is still found very effective, and is being generally adopted.

This and the following issue of the same journal contain the final instalments of an account, by D. L. Lehmann, of the developments in the subject of artificial organic dyestuffs.

For the cure of men who have accidentally inhaled gas or air containing carbon monoxide, the application of oxygen is officially recommended in the issue for June 15, and it is laid down that a cylinder of compressed oxygen and a proper mouthpiece be always kept near to suction gas plants and other plant where there is any danger of carbon monoxide escaping. In the same issue there is also a discussion between Weigelt and Lauterborn, on effluents in the Rhine.

In the second number of the *Kriegs-technische Zeitschrift*, there is an interesting article in explanation of the destruction of the bore of guns by the use of nitrate powders. The writer, W. Kiever, ascribes the action to the occlusion of gases under the influence of high temperature and pressure. If the temperature and pressure be sufficiently high, the amount of gas dissolved or occluded by the iron is so great that when the pressure of gas has fallen off outside the metal, that of the gas which is in the metal is sufficiently high to disrupt it and cause ruts in the surface. This action being repeated each time the gun is fired, gradually scores deeply into the bore, the effect being increased by the mechanical action of the projectile. To prevent this destruction of big guns, the author suggests that the steel might be alloyed with some metal, such as magnesium, which would combine chemically with the nitrogen that is forced into the metal, and form a solid compound that would have a less injurious effect than the gas. Alternatively, he proposes to wash the bore out with an alkaline material before each shot.

An interesting obituary of Prof. Mendeléeff is contributed by Saposhnikoff to the *Zeitschrift für das Gesamte Schiess- und Sprengstoffwesen*, for May 1, special attention being of course devoted to the contributions that the deceased scientist made to the subject of explosives. Microphotographs are given to show the difference between Mendeléeff's pyrocollodion powder and a pyroxylin powder.

In the same issue, C. E. Bichel writes on the recent accidents at Courrières, Reden, and Klein-Rosseln, and their effect on the examination of safety explosives in various lands. These accidents are all to be ascribed to the explosion of coal dust suspended in air rather than of fire-damp. Bichel, who is himself a manufacturer of certain types of explosives which pass the tests that are laid down in Germany and certain other Continental countries, deprecates the difference of the English regulations, and expresses the hope that our test will be abolished in consequence of the investigations of the "Bobbinite" Commission and the Royal Commission on Safety in Mines, and that we shall adopt the Continental system.

The investigation of the relative values of different manures is a problem of such complexity that additional investigations are always to be welcomed. The number of factors that may be altered are so many—soil, climate, plant, and treatment—that the fertiliser which is most effective under one set of conditions is not necessarily so under another. In the *Zentralblatt für die Kunstdünger-Industrie*, for May 21 and June 7, there is an account of some comparative experiments carried out by J. Sebelien with the new fertilisers, nitrate of lime and calcium cyanamide. The results showed that under the selected conditions nitrate of lime was in most cases equal or nearly equal to Chile saltpetre, and better than ammonium sulphate, whereas the cyanamide had comparatively little effect.

Indian Notes.

Market movements (Calcutta, June 5) are reported as under:—

Castor oil cake.—The market is very firm. For export, quotations are Rs.6.4 for picked and Rs.5.15½ for average quality, per bag of 2 maunds, f.o.b. Stocks and supplies continue very moderate.

Bone meal.—The market is quiet and very little doing; sellers, however, remain firm and quote Rs.73.0 for quality required by the New Zealand Government, Rs.68.0 for usual standard of steamed quality, and Rs.62.0 for usual standard of unsteamed quality, per ton of 20 cwt., f.o.b., guaranteed 4½% ammonia and 52% tribasic phosphate of lime, for near shipment. Bone dust is very steady at Rs.54.0 for steamed, and Rs.52.0 for unsteamed quality, guaranteed 3½% ammonia and 40% tribasic phosphate of lime, for near and early deliveries. Offerings continue moderate.

Beeswax (season, September to June).—Notwithstanding the scarcity of export orders, and owing to the short supplies being barely sufficient for ordinary local requirements, the market keeps very stiff. Quotations: Rs.78.0 to Rs.80.0 for refined quality, and Rs.70.0 to Rs.78.0 for raw, per bazar maund weight, loose, for prompt delivery. No sales for Europe are reported.

Saltpetre (season, September to June).—Market is dull, but sellers keep rather firm and do not reduce their prices. For refined Furreckabad Rs.8.8 to Rs.9.0, and for ordinary 5% refraction quality Rs.8.0 to Rs.8.2 per factory maund weight, loose, for near and early deliveries. Supplies are moderate. Offers of superior lower refraction qualities are small, as usual, at this period of the season.

Borax.—The market has kept very steady but without animation; quotations are Rs.14.12 to Rs. 15.8 per bazar maund weight, loose, prompt delivery. Stocks and supplies are small.

Turmeric (season, March to September).—Bengal turmeric, suitable for Europe, is quoted Rs.6.10 per bazar maund weight, loose, for June-July deliveries.

The salt market closed easy. Local stocks held, in maund weights, were reported ex Liverpool 393,826, Hamburg 199,386, Aden 99,163, Saliff 138,189, Spanish 227,853, Port Said 108,565, and Bombay 77,755. Quotations per maund were: Liverpool Rs.53.0 to Rs.62.0, Hamburg Rs.55.0 to Rs.58.0, Aden Rs.51.0 to Rs.63.0, Saliff Rs.50.0 to Rs.70.0, Spanish Rs.53.0 to Rs.67.0, Port Said Rs.57.0 to Rs.66.0, and Bombay Rs.65.0.

Castor oil.—There has been some movement in this market, and about 5,000 packages have been placed on the basis of Rs.19.8½ for Fine Pale, Rs.13.12½ for good seconds, and Rs.13.2½ for thirds, in cases, per bazar maund weight, f.o.b., for this and next month's deliveries. Sellers generally are holding off for higher prices. Market closes quiet. Offerings are very moderate.

Cocoanut oil.—Market quieter, rates easier; for export, prices are Rs.22.14½ per bazar maund weight, f.o.b. Stocks are light, but supplies have been increasing slowly.

The cultivation of camphor is being tried in certain forests of the Kanard range by the Bombay Forest Department. A difficulty exists in obtaining the seeds in any quantity, as the Japanese, who possess the true species—*cinnamomum camphora*—have always endeavoured to prevent the export of the seed. In Japan, the seed costs 2s. 6d. per lb. November is said to be the month to obtain fresh seed, and as it does not last long, it is sent by post and sown immediately on arrival.

Gopeng Tin Co., Ltd.—The directors have declared a dividend of 1s. 6d. per share.

Fire at an Oil Works.—On Sunday evening last, a serious fire broke out at the works of Messrs. Dawson, Ltd., oil and chemical manure manufacturers, Grimsby, the buildings being gutted, with the exception of the drying chamber.

THE ALKALI INSPECTOR'S REPORT.—IV.*

SALT WORKS.

The amount of muriatic acid escaping into the atmosphere from this class of work is maintained at a figure well within the maximum prescribed by the Provisional Order Confirmation (Salt Works) Act, 1884. The limit is the same as that prescribed for alkali works, viz., one-fifth of a grain of muriatic acid per cubic foot of chimney gases. The average escape is 0.055 grain.

The number of such works is now 53, as compared with the same number in 1905. The vacuum method of evaporation of brine has attained considerable development in two large works. In these no muriatic acid gas is evolved.

Dr. Attleck continues to speak with approval of the developments in the use of Mond producer-gas as fuel at one work. The expectations previously formed as to economy appear to have been realised. The even heating of the gas-fired pans contributes in maintaining at a satisfactorily low figure the escape of muriatic acid at this work.

From the official returns on Mines and Quarries (Part III.), the total output of white salt produced from brine and salt contained in brine used for making alkali by the ammonia-soda process was, in 1905 (the latest date for which returns are issued), 1,658,364 tons, as compared with 1,703,805 tons in 1904. There was again increase recorded in Lancaster and Durham, but heavier decreases occurred in Chester and Stafford, and also in Yorkshire on the Middlesbrough side of the River Tees.

At the commencement of 1907, by the operation of the new statute the repeal is effected of the Act to confirm the Provisional Order issued by the Local Government Board in 1884 with regard to salt works.

Salt works will for the future be classed as Muriatic Works (*c*), paragraph 8 of the first schedule. This class of work is therefore subject to exactly the same obligations as hitherto since 1885.

The chief statutory obligations are rehearsed in Sections 6 and 7 of the 1906 statute. It will be noted that the definition of salt works excludes those in which salt is obtained without evolution of muriatic acid in the process for its extraction from brine.

ARSENIC WORKS.

There is considerable activity in this class of work at the present time; moreover, new sources of supply have been developed during the past year, by which some addition, though not a large one, has been made to the quantity of white arsenic available for industrial use. The large contributor still remains the output from Cornwall, which in 1906 amounted to 1,599 tons, as compared with 1,528 tons in 1905.

Dr. Fryer, in his district report, gives some interesting statistics concerning the world's production of arsenic.

The number of works for production of arsenious and arsenic acids has increased during the year to 35, compared with 27 in 1905.

As regards arsenious acid, or white arsenic, the number of such works registered in Cornwall and South Wales fell in 1905 to 19, the lowest figure recorded since 1893, when such works were first scheduled under the Alkali Act, 1892.

In the Widnes and Runcorn district 3A, on the other hand, the number has increased from 1 to 5 by the operations of new and patented processes of manufacture by which arsenious acid is recovered in very pure form from arsenical vitriol produced from highly arsenical pyrites. Improvements in the efficiency of the process have resulted from the careful study devoted to it by those responsible for its development, so that its extension during 1907 is assured.

As, in the operation of the process the arsenic is volatilised from the acid as arsenious chloride, very special precautions are necessary in the designing and working of plant on account of the poisonous properties of the substances dealt with.

In concluding his report, the Chief Inspector says:—"Although not coming strictly within the year under review, the retirement of Dr. Attleck from the public service may appropriately find regretful mention here, the report he presents on pp. 82-90 being the last that he will make of the work of his department, his retirement, dated February 9, occurring during the progress of preparation of this report. Since 1884 he has had charge of the important district of Widnes and Runcorn, where an especial amount of responsibility rests upon the inspector owing to the magnitude of scale of chemical manufactures conducted there, and to the nature of the gases evolved. Before his appointment Dr. Attleck had already gained wide experience, which he was enabled to apply with advantage to the various problems that confronted him. His reports constitute a valuable record of progress over a period approaching a quarter of a century; in these, moreover, he has borne constant testimony to the loyal co-operation of the manufacturers in the administration of the Acts, and in the endeavours made to reduce to a minimum the escape of noxious and acid gases from the various scheduled processes conducted. I have personally received much assistance from the collaboration and criticism on difficult problems that his matured experience enabled him, always willingly, to render."

*The 43rd Annual Report on Alkali, etc., Works, by the Chief Inspector. (See *C. T. J.*, Nos. 1,046, 1,048, and 1,049, pp. 529, 580, and 603.)

MINERALS IN GREECE.

IN his report on the mining trade of Greece for 1906, Consul Mr. MacDonell observes that British merchants might, with profit, turn their attention to the mineral deposits of Greece. During 1906 exports of chrome ore have taken place from the Lamia district, and both in this district and adjacent islands are important deposits of chrome hitherto unworked. The ores show 30% to 50% oxide of chrome and average about 4% silica. Large deposits of magnesite and various other iron ores exist in Enboca and on the mainland, all of which, in the near future, will be of value. Copper is also found in small quantities.

Mr. Vice-Consul Desposito reports that, in Laurienne, mining operations have been carried on during the last year. The actual output has exceeded that of 1905. The surface yield for 1906, after mechanical dressing, was reduced to 73,348 tons; this, added to the underground ores, makes up a total of 180,102 tons, which yielded at the foundries 12,127 tons of metallic lead, with an average, per ton, of 1,504 to 1,793 grammes of silver. The following table shows the quantity of minerals and metallic lead exported during 1900-06.

	1900.	1901.	1902.	1903	1904.	1905.	1906.
	Tons	Tons.	Tons.	Tons.	Tons	Tons.	Tons.
Silver pig lead ..	16,783	16 458	16,368	15 9 8	15 370	13 397	12 387
Raw and roasted manganese iron ore	234,94	199 135	152 253	147.475	22 125	121,585	130,652
Hematite iron ore..	171,287	113,375	113,202	121,380	100,045	96,929	111,735
Roasted calamine or zinc ore	13,519	15,717	19 445	12,549	21,034	20.051	23,732
Speiss .	1,632	2,416	2,500	2 156	484	..	3,068
Lead smokes ..	2,247	2 197	1 896	2,121	1 384	..	1,553
Blende of lead and zinc ore .. .	1,424	455	1,418	732	366	..	920
Total	442,041	349,753	307 087	302 361	263,778	253,962	284,047

UNITED INDIGO AND CHEMICAL COMPANY.—The directors of this company have decided that it was not advisable to pay the preference dividend on the 30th ult., but to wait until the accounts for the year ending the 30th ult. are made up and the annual meeting held.

FRENCH REVENUE RETURNS.—The revenue from taxation and monopolies during May amounted to 232,878,500f., showing an increase of 1,432,700f. compared with the Budgetary estimate for the month, and an increase of 9,520,900f. as compared with the receipts for May, 1906. The revenue for the first five months of the present year shows an increase of 93,718,800f. compared with the Budgetary estimate.

PHOSPHATE IN JAPAN.—H.M. Consul at Shimonoseki reports that a very interesting feature of last year's import trade at that port was the arrival of the first shipment of phosphate rock from Christmas Island. During the year a company, the Osaka Ryuso Kabushiki Kwaisha (the Osaka Phosphate Company), was formed with the object of manufacturing superphosphates for fertilising purposes. Phosphate works were established at Fuku-ura on Hikoshima, an island at the western entrance to the Straits of Shimonoseki; and the first shipment of phosphate rock from Christmas Island arrived on August 20. The amount imported during the year was 5,459 tons in quantity and £18,255. in value.

Analytical Notes.

A NEW METHOD FOR ESTIMATING THE ALKALINITY OF ASHES.*

By K. Farnsteiner (*Zeit. Untersuch. Nahr. Genussm.*)

It is well known that the estimation of the alkalinity of an ash by direct titration is considerably influenced by the presence of phosphates, this influence being due to the effect of the phosphates on the indicator used, and also, if the alkalinity of the soluble ash be under consideration, to the varying solubilities of these salts. To overcome this difficulty, the author proposes a method in which the ash is dissolved in a known volume of standard acid; the phosphates are precipated by the addition of calcium chloride and a known quantity of ammonia, and the excess of ammonia is then titrated back. The alkalinity of the ash is calculated from the equation, $a = S + s - n$, where a is the weight (in grams) of the ash, S the number of c.c. of $\frac{N}{1}$ acid used for dissolving the ash, s the number of c.c. of $\frac{N}{1}$ acid used in the final titration, and n the number of c.c. of $\frac{N}{1}$ ammonia added. The details of the process are as follows: From 0.2 to 0.3 gramme of the dry ash is gently boiled for about three minutes in a flask with 20 c.c. of $\frac{N}{2}$ hydrochloric acid and about 40 c.c. of water. When cold, the contents of the flask are rinsed into a stoppered graduated cylinder, 100c.c. of a solution containing 5% of dry calcium chloride and 10% of ammonium chloride are added, and then 20 c.c. of $\frac{N}{2}$ ammonia. The volume of the liquid is made up to 100 c.c. with water free from carbon dioxide, and, after mixing its contents, the cylinder is placed aside overnight. Finally 50 c.c. of the clear supernatant solution are pipetted off and titrated with $\frac{N}{10}$ hydrochloric acid, using methyl orange as indicator.

The results obtained by the above method are usually much lower than those given by the direct titration method, ashes containing much pyrophosphate even exhibiting a "negative" alkalinity.

THE ESTIMATION OF FREE ACIDS IN SUPERPHOSPHATES.*

By J. van Dormael (*Bull. Soc. Chim. Belg.*)

The following method, embodying those of Herzfelder and Thomson, is recommended as rapid and exact: 5 grammes of the sample, previously dried for three hours in the hot-water oven, are shaken in a stoppered flask with 100 c.c. of ether or alcohol (preferably the former) at intervals during a period of three hours. The extract is then filtered, 50 c.c. of the clear filtrate evaporated to dryness, the residue taken up with water, and the liquid filtered if necessary. The solution is now treated with a few drops of methyl orange, and titrated with $\frac{N}{4}$ sodium hydroxide solution until the colour changes to yellow, after which the titration is finished with phenolphthalein as indicator. The reactions in the two titrations are as follows:

(1.) $H_3PO_4 + NaOH = H_2NaPO_4 + H_2O$.
(2.) $H_2NaPO_4 + NaOH = HNa_2PO_4 + H_2O$.

In the absence of any considerable amount of sulphuric acid the whole of the sodium hydroxide consumed may be regarded as neutralising only free phosphoric acid. As a rule, free sulphuric acid is negligible; of twelve samples examined by the author, it was present in only two, and then in quantities of less than 0.5%.

A NEW METHOD OF ESTIMATING AMMONIA IN WATER.*

By A. Buisson (*Journ. Pharm. Chim.*)

The method is based upon the fact that, on adding sodium carbonate to the solution of an ammonium salt containing mercuric chloride in the proportion of 5 molecules of mercuric chloride to 2 of the ammonium salt, the ammonia is quantitatively precipitated.

The white amorphous precipitate has the composition $CO_3(Hg_5N_2Cl_2)_3O + 3H_2O$; it loses water when dried in a current of air at 100° C., meanwhile turning yellow. It is not altered by water at the ordinary temperature, but begins to decompose at about 80° C.,

For the determination of ammonia in water by means of this reaction, a litre of the sample is rendered alkaline with 5 c.c. of pure sodium hydroxide solution (1 : 4) and distilled, and the distillate received in 10 c.c. of 1% hydrochloric acid. The distillation should continue for at least an hour, and the amount of distillate should be rather more that 100 c.c. It is diluted to a litre, and shaken with 10 c.c. of a 5% solution of mercuric chloride, and the ammonia precipitated by the addition of 10 c.c. of a 15% solution of sodium carbonate. After standing for twenty-four hours, the precipitate is collected on a filter of glass wool in a Soxhlet's tube, washed with 5 c.c. of water, dried at 100 C., and weighed. The weight of the dry precipitate multiplied by the factor 0.03 gives the amount of ammonia in a litre of the water. If the proportion of ammonia in a water is less than 1 mgm. (as shown by Nessler's reagent), the precipitation should be made by the addition of 1 c.c. of the reagents to the 100 c.c. of distillate without dilution to a litre. In test experiments 0.158 mgm. and 9.53 mgms. of ammonia in the form of pure dry ammonium chloride were added to pure water, and 0.149 and 9.51 mgms. found respectively.

SEPARATION OF COPPER FROM OTHER METALS BY MEANS OF ACETYLENE.*

By H. Erdmann and O. Makowka (*Zeit. anal. Chem.*)

Copper may be readily separated from other metals by means of acetylene, cuprous acetylide being formed when acetylene is passed into an ammoniacal or feebly acid solution of a cuprous salt. Cupric salts must be reduced by means of hydroxylamine hydrochloride in ammoniacal solution before proceeding with the precipitation. For instance, a weighed quantity of copper sulphate is dissolved in water, ammonia is added, and then sufficient of the reducing agent to decolorise the solution. Acetylene is passed into the mixture for about twenty minutes, the precipitate is collected on a filter, washed with water, and then dissolved in nitric acid; the solution is evaporated to dryness, and the residue weighed, after ignition. If it be desired to separate copper from mercury or silver, it is necessary to remove these two metals before precipitating the copper with acetylene, in which case mercury is preferably separated by means of phosphorous acid and silver by hydrochloric acid. Copper is best separated from calcium, strontium, barium, magnesium, cadmium, zinc, aluminium, iron, and lead in dilute acetic acid solution, and from chromium, manganese, nickel, cobalt, bismuth, antimony, arsenic, and tin, in ammoniacal tartrate solution. The separation of copper from palladium is based on the fact that palladium is precipitated in strongly acid (hydrochloric) solution by acetylene (*Analyst*, 1904, 29, 382). This property of palladium enables it to be separated from platinum and iridium. Gold is also precipitated from acid solutions by acetylene, and in the case of a mixture of gold and palladium salts, both metals are precipitated together, being afterwards separated by dissolving out the palladium with hot nitric acid.

NITRATE OF SODA.

THE June shipments to Europe, to some extent curtailed by the lock-out at Taltal, were only 52,100 tons, against 70,500 tons last year, the quantity "loading" on 1st inst. being 114,500 tons, compared with 102,650 tons twelve months ago. Although the imports were nearly twice as large as in June, 1906, the European deliveries are modestly computed at 74,680 tons, or only 2,180 tons more than last year, the total "visible supply" coming out at 291,460 tons, compared with 276,550 tons a year ago. The surplus is thus reduced to the insignificant figure of 14,910 tons, but "stocks at ports" are officially stated at 132,960 tons, against 55,820 tons at this time last year, and the "invisible" stocks at interior points are admittedly considerably larger. The market is devoid of interesting features, spot business being conspicuous by its absence, while transactions afloat are limited to a single cargo of refined quality during the past fortnight. Prices are still nominal, but rather easier, prompt nitrate being quoted at 10s. 10½d. per cwt. in Hamburg, and next spring delivery 11s. 3d. On the West Coast the quotation is about 9s. 1d. per quintal, f.o.b., for summer shipment, with no business passing. Last month's exports of nitrate from Chili to the United States beat all previous records, and are causing much jubilation in trade circles. The past half year will be reviewed in an early issue of this *Journal*.

Beet Sugar.—Since the announcement of the Government policy with regard to the Brussels Sugar Convention, the project for the establishment of a beet sugar factory in Lincolnshire has been abandoned.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in the Method of Burning or Calcining Calcareous and Argillaceous and Mineral Substances in Rotary Furnaces or Kilns. B. H Thwaite. 29, Great George Street, Westminster, London, S.W. British Patent, 15,677. July 11, 1906.

The inventor claims:—(1.) In the burning or calcining of calcareous and argillaceous and mineral substances in rotary furnaces or kilns, the application of powdered carbonaceous fuel injected into the combustion chamber to meet a flow of superheated air and a flow of producer gaseous fuel in the manner and for the purpose. (2.) The increasing of the temperature of combustion of producer gaseous fuel and powdered coal or either of them by the introduction of preheated air to support and increase the temperature of combustion for the effective and economic burning of cementitious materials in rotary kilns, the preheating of the air being effected by diverting part of the gaseous fuel for such purposes. (3.) The combination with rotary furnaces or kilns for burning or calcining cement and allied purposes, of the means or apparatus employed for securing a highly intense and lengthened flame extending through the kiln, as accompanying the specification.

Improved Process for Oxidising Liquids with Aid of Electric Discharges. A. de Hemptinne, 51, Rue Basse des Champs, Gand, Belgium. British Patent, 13,023. June 5, 1906.

The inventor observes that hitherto the oxidising properties of ozonised oxygen or air have been applied to liquids by first ozonising the oxygen or air in an apparatus worked by the silent electric discharge, and then bringing the ozonised gas into contact with the liquid on which it is to act. The gas and liquid are brought into contact either by bubbling the former through the latter, or by finely pulverising the gas and liquid in a special chamber.

According to the present invention, the electric discharge is caused to act directly on a thin layer, preferably in motion, of the liquid to be treated while the latter is in direct contact with the gas. The electric discharge traverses the thin layer of liquid and the gas, which, being ozonised, instantaneously oxidises the liquid, this action being particularly rapid and energetic.

A suitable apparatus for the treatment of liquids according to the invention comprises a cylinder within which are mounted, preferably co-axially with the cylinder, a series of parallel plates, alternately of an electrically conducting material such as metal, and of electrically insulating material such as glass. These plates are situated some millimetres apart; the metal plates which are of uneven number in the series of metal plates are electrically connected with each other, and with one pole of a suitable source of electrical energy, the metal plates of even nymber being similarly connected with each other and the other pole of the source. The interior surface of the cylinder is provided with a number of gutters, which, as the cylinder is rotated, continually carry up the liquid and discharge it over the upper part of the plates so as to form on the latter thin moving layers of liquid. The cylinder is filled with oxygen or air and the electrical energy is supplied; the oxygen is ozonised and oxidises the liquid. The apparatus is stopped from time to time to receive a fresh charge of oxygen, and is provided with the necessary cocks for introducing oxygen and drawing off the liquid. The apparatus may be heated.

The mode of carrying out the invention may be varied; such as by placing the insulating plates in contact with the conducting plates; or by varying the manner in which the plates are sprinkled with the liquid, for instance, by having fixed plates and sprinkling these at their upper part. The process is applicable for transforming fish oils into dégras, for purifying waters, for ageing alcohol, for transformation and oxidation of oils, and for the manufacture of perfumes.

Improvements in Apparatus for Treating Minerals by Electrolysis. N. H. M. Dekker, 29, Rue de la Soudière, Paris. British Patent, 5,887. March 11, 1907.

This invention relates to apparatus for electrolytically treating mineral comprising horizontal anodes and cathodes alternately arranged in a receptacle having an orifice for the discharge of the gases evolved, with insulators placed between the consecutive elements or couples, alternate electrodes being provided with frames or upwardly projecting walls to form boxes for the mineral to be treated, and insulating supports or distance pieces being placed on said frames to support the electrodes between the framed electrodes.

BIRTHDAY HONOURS.—The list of honours issued on the occasion of the King's birthday contains the following appointments:—Peerage: Right Honourable Sir James Kitson, Bart., M.P. (President of the Iron and Steel Institute, 1888-90). Baronet: Sir W. H. Holland, M.P. (formerly President of the Associated Chambers of Commerce of the United Kingdom). Knighthoods: Principal James Donaldson (University of St. Andrews). K.C.B.: Prof. Edwin Ray Lankester, LL.D., F.R.S. Order of the Indian Empire: Major David Melville Babbington (Royal Artillery, Superintendent of the Cordite Factory, Wellington).

The Revenue Returns.—The Treasury returns for the first quarter of the financial year show a total revenue of £40,095,837., with a deficiency of £2,018,455. The quarter, as compared with the corresponding quarter of the preceding year, shows a net increase of £813,701. Customs showed a decrease of £236,761.; Excise, an increase of £92,603.; estate, etc., duties, an increase of £148,921.; stamps, an increase of £14,000.; house duty, an increase of £50,000.; property and income tax, an increase of £473,000.; Post Office, £110,000.; Telegraph service, an increase of £40,000.; receipts from Suez Canal shares and sundry loans, an increase of £2,500.; and miscellaneous, an increase of £119,438.

Secret Commissions and Bribery Prevention.—At a meeting of the Council of the Secret Commissions and Bribery Prevention League, held on July 2 at the London Chamber of Commerce, Sir Edward Fry was elected as first President, and the Archbishop of Canterbury, Earl Fortescue, Lord Avebury, Sir W. H. Holland, Sir W. Mather, and Mr. David Howard were elected Vice-Presidents. Mr. David Howard, who presided, was able to report that the League had made considerable progress, and was obtaining an increasingly influential membership. Mr. R. M. Leonard having been recently appointed secretary, the offices of the League have been removed now to 3, Oxford Court, Cannon-street, London, E.C.

OBITUARY.

We regret to record the death, which took place on Sunday last, of Mr. Frederick Herbert Gossage, J.P., the head of the firm of William Gossage and Sons, soapmakers.

The *Liverpool Daily Post* says :—" By the death of Mr. Gossage a serious public loss has been sustained by both Liverpool and Widnes. The business which he controlled, now of world-wide reputation, was established by Mr. William Gossage, a manufacturing chemist of distinguished ability. Mr. F. H. Gossage was the third son of Mr. W. Gossage. He joined his father in the conduct of the business, which was carried on at Widnes. Mr. F. H. Gossage inherited his father's insight and initiative. At different times he patented important new processes, which introduced still further economics into the manufacture. The association, however, in which his name will long deserve to be remembered is the development of those facilities now offered by Liverpool University for practical training in science, to obtain which, not many years ago, chemists more especially were obliged to have recourse to German universities. In a great centre of chemical industry like Liverpool this was something of a reproach, but it has been most generously removed. Mr. Gossage, Sir John Brunner, Dr. Ludwig Mond, Mr. T. Sutton Timmis, Mr. E. K. Muspratt, and Mr. W. H. Lever have collectively placed the chemical department of the University abreast of the most advanced science. Towards this great work Mr. Gossage, in association with Mr. Timmis, contributed the Quantitative Laboratory, a necessary and integral part of the design. The laboratory was given as a memorial—one particularly fitting—of the late Mr. W. Gossage. It was built at a cost of £7,000., and formally opened in December, 1896. The other gentlemen already named contributed the Specific Laboratory, the outfit of the metallurgy department, the hydraulic apparatus, and other necessary accessories. Personally, Mr. Gossage was, besides his distinguished attainments as a chemist, a well-read and cultivated man, singularly upright and fair-minded, and in cases of which the public knew nothing his benevolence and generosity were unstintingly exercised. He was a genial host, and his residence at Camphill, Woolton, gave evidence of his refined taste and discriminating love of art. Mr. Gossage, who was twice married, leaves a widow, six sons, and three daughters."

The death also occurred last week of Mr. Hamor Lockwood, well known in the Manchester district as a manufacturing chemist.

Answers to Correspondents.

We cannot undertake to reply to correspondents through the post. Those of our readers who have addressed queries to us should look in this column for a reply.

B.W.—We suggest that you address your letter to the gentleman mentioned, under cover to the Editor, Professor Schuberg, *Zeitschrift für Chemische Aparatenkunde*, Goethstrasse 8, Charlottenburg, Germany.

A.M.—Thanks for your letter. We are transmitting the information to our subscriber.

W.W.B.—We note contents of yours of the 2nd inst. MSS. also to hand.

W.J.K.—Thanks for yours of the 3rd. We note your second paragraph, which we will keep in view.

The Royal Agricultural Show was held last week at Lincoln, and was opened by His Majesty the King. The attendance was large, and, together with the record at the Derby Show last year, completes the contrast with the very small figures in London during the disastrous permanent show-yard experiment. The exhibits in the various classes were satisfactory, and, on the whole, the success of the 1907 Show marks a further stage in the re-establishment of the prosperity of the Royal Agricultural Society.

Nitrate Statistics.—The Permanent Nitrate Committee, in their public statistical circular for July, state the shipments of nitrate of soda as follows :—(1.) Total exports to Europe, June, 1,146,300 quintals. (2.) Imports, Europe, June, 135,380 tons. (3.) Deliveries, Europe, June, 74,680 tons. (4.) Visible supply, Europe, July 1 : Stocks and afloat, 291,460 tons.

NEW YORK PRICES CURRENT.

June 17, 1907.

Prepared for this Journal by Messrs. Stanley Jordan and Co., 100, William-street, New York.

Market Reports.

TAR AND AMMONIA PRODUCTS.

Friday.

Benzols quiet, with values given at 9d. for 90's, and 9½d. to 9¾d. for 50-90's. Crude tar, 16s. to 20s. per ton, Thames ; 1½d. to 1⅝d. per gallon delivered. Refined tar, 12s. per barrel ; Gas Company, 12s. 6d. Pitch, London, 26s., f.o.b. ; Gas Company, 30s. 6d. ; East Coast, 25s. to 25s. 6d. ; West Coast, 24s., next year 2s. 6d. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 1s. 1d. to 1½d. ; pure, 1s. 8½d. to 1s. 9d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5½d. ; 60%, 1s. 7½d. to 1s. 8d. ; 75%, 1s. 11½d. to 2s. ; crystals, 39-40, 5¾d. ; 34-35, 5½d. Cresylic, 95%, 1s. 1½d. to 1s. 2d. Anthracene, 40 to 45%A, 1½d. to 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quietly steady. Nearest values are :—Beckton, £12. 2s. 6d. to £12. 5s. ; Beckton terms, £11. 13s. 9d. ; London (outside makes), £11. 17s. 6d. ; Hull, £11. 15s. ; Liverpool, £11. 17s. 6d. to £11. 18s. 9d. ; Manchester, £11. 15s. to £11. 16s. 3d. ; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d. ; Liverpool, ordinary, 11s., and refined, 11s. 3d. Official quotations :—Cargoes off coast or due, 10s. 11½d. ; ditto, for prompt shipment, 11s.1½d.

FERTILISER MATERIALS.

Thursday.

The manure season being now over, manufacturers are at liberty to consider further purchases of material for the next compaign, but they are in no hurry about it. They are practically covered in regard to phosphate rock, so that any business doing in that article is for delivery further ahead. Prices are firm for all grades.

Digitized by Google

Not much interest is being taken in East Indian bone meal for shipment to United Kingdom, but notwithstanding this Shippers are firm at £5. 2s. 6d. per ton, nett, c.i.f. Liverpool. On spot, £5. 7s. 6d. to £5. 12s. 6d. per ton is required, ex store, according to quality.

Nitrate of soda is a quiet market, but quotations remain steady at 11s. per cwt. for 95%, and 11s. 3d. per cwt. for refined quality.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, June 17, 1907.

(Rate of Exchange, $4.87½ = £1.)

Nitrate of soda shows more strength for shipment, and the price is now $2.55. Spot goods are somewhat more plentiful, and are offered at $2.75. Sulphate of ammonia is $3.05 per 100 lbs. Grey muriate is steady at 66½c. as to make, and white electrical is quoted from 6c. to 6½c. Carbonate of ammonia, lump, ranges from 7⅝c. to 8c. per lb., and powdered nominally 1c. per lb. higher. Lump salammoniac, good white seconds, is 9½c. Sulphate of copper is 7⅜c. to 7½c., and very dull. White powdered arsenic is practically without demand for prompt shipment, but futures hold firm at 7⅜c. to 7½c. Red Saxony arsenic is steady at 7½c. Bleaching powders at from $1.20 to $1.30. per 100 lbs. Alkali is 92½c. per 100 lbs., f.o.r. maker's works, for light 58% in bags. Caustic soda, 74%, is a trifle weaker, at $2.07½. per 100 lbs., same conditions. Calcined carbonate of potash, 80-85% is slow at 3¾c., and hydrated at 4⅜c. Caustic potash, 75%, is 4¼c. Chlorate of soda is 8½c., and potash 8⅛c., both f.o.r. maker's works. Bichromate of soda has been advanced 1c. per lb. to 7⅜c., and potash advanced ⅛c. to 8⅛c., following a convention of the makers. Prussiate of soda inclined to be weak at 10c., and potash is slow at 16c. per lb. Oxalic still remains slow, and sells from 8¼c. upwards. Needle antimony is weak at 9½c. for lump, and all antimony compounds have a downward tendency. General business is very slow, and there is not much pressure to sell.

THE LONDON METAL MARKETS.

Thursday.

Copper: Standard brands, £99. 5s. to £99. 10s. cash, and £93. 10s. to £93. 15s. three months. Tin: G.M. quality, £198. to £198. 10s. cash, and £184. to £184. 10s. three months; English, £194. Lead: Soft foreign, July, £21. 5s.; August, £21.; September, £20. 12s. 6d.; October, £20. 10s.; English, £21. 10s. to £21. 15s. Spelter: ordinary brands, £24. to £24. 5s., ex ship; hard, £20. 10s., f.o.b. Antimony, £45. to £48.; ore, £8. to £10. Bismuth, 5s. Quicksilver, £7.; seconds, £6. 16s. Nickel, £175. to £185. Pig-iron closing prices:—Standard, 56s. 7d. cash, and 56s. 10½d. one month; Cleveland, 56s. 10d. cash, and 57s. 1d. one month.

MISCELLANEOUS CHEMICAL MARKET.

Thursday.

For the products of the alkali trade and heavy chemicals generally a fairly good demand is maintained; but there is no accession of business beyond the ordinary demand, and upon the whole the spot markets are quiet. In the alkali trade prices remain steady, and are practically without change. Bleaching Powder is £4. 7s. 6d. to £4. 10s., f.o.r. and f.o.b. for prompt and forward delivery. Some inquiry is on foot for next year's requirements. Saltcake is steady in price, and demand continues active at 40s. per ton, f.o.r. Chlorates unchanged at 3½d. Caustic soda, 70%, £9. 15s., f.o.b. Alkali, 58%, in bags, £4. 10s. per ton. Soda crystals, 60s. per ton. Potash, caustic and carbonate remain firm in price, and demand is good. Prussiate of potash, 6d., and soda, 3¾d. per lb. Acetic acids in all qualities are selling freely and prices are firm. Acetate of lime, grey, 80%, is steady at £12. 10s., c.i.f. Sugar of lead is quiet. Arsenic is more freely offered at £33. 10s. to £34. Sulphate of copper rather easier at £31. 5s., f.o.b. Sulphites of soda are firm and in good request. Ammonia muriate is scarce at prices ruling from £24. to £25. per ton.

LIVERPOOL DRYSALTERIES.

Thursday.

Montreal potashes dull, at 35s., and pearl ash, 40s. per cwt.; bark steady, but with little offering. Berries in better request, with Persian quoted 55s. per cwt. Logwood and fustic quiet, with prices maintained. Cutch quiet, at full rates. Beeswax: A parcel of Sierra Leone sold in store at £7. per cwt. Castor oil firm, at 3 1/16d. for good seconds Calcutta, on spot, and for June-July shipment; first pressure French, 3½d. to 3¾d.; second pressure, 3¼d. Gambier: Block quietly steady, at 19s. to 19s. 6d., on spot, and 17s. 9d. for June-July and July-August shipment; cubes, 28s. to 28s. 6d., spot, and 27s. 9d. for June-July and July-August shipment. Shellac dull, with fair free TN Orange selling at 211s. on spot, August, 205s., and October, 195s.; AC. Garnet, 207s. 6d. on spot, October, 186s., and November, 184s. to 185s.; fine marks orange, 227s. 6d. to 240s.; GAL, 190s. to 192s. 6d. Glucose: American liquid, 43%, 10s. 6d. on spot, and 8s. for June shipment; chips, 80%, 8s. 3d.; 70%, 8s., c.i.f. American powdered starch, 10s. on spot, and 9s. 6d. for shipment; pearl, on spot, 9s. 4½d., and for shipment, 9s., c.i.f. Cream of tartar: 98% foreign powder, 82s.; 95%, 80s. Citric acid: English, 2s. 0½d.; foreign, 1s. 11½d. to 1s. 11¾d. Tartaric acid: English, on spot, 11¼d.; foreign, 11¼d.

LIVERPOOL OIL AND COLOUR MARKET.

Thursday.

OILS.—Palm oil dull, sales including Grand Bassa and Dixcove on spot and near arrival, at £28.; Accra, £29. 7s. 6d., on spot and near, £29. 15s.; Niger, £29. 10s., on spot; Benin, spot, £30.; June-July and July-August, £30.; near arrival, £30. 10s.; Old Calabar, spot, £30. 10s., and June-July, £30. 15s.; soft oils, £30. 12s. 6d.; Emoe, £30. 17s. 6d.; Lagos, £31. 10s. to £31. 5s., on spot, and £31. 5s. for near arrival; Saltpond, June-July, £28. 5s., near arrival, £28. 7s. 6d.; Sherbro, July-August, £29. 15s. per ton, all in transit. Olive oil in fair request, at £40. to £42. 10s. per tun; shipment parcels, £37. to £38., c.i.f. for Levant, and £37. per tun for Corfu. Tallow quiet at 33s. to 38s. on spot, for North American beef; South American beef, 37s. to 37s. 6d., and mutton, 37s. 6d. to 38s.; Australian, 34s. 6d. to 36s. 6d. for mixed and beef; mutton, 37s. to 38s. 6d.; home melted, 33s. 6d. to 37s. 6d. per cwt. Rosin steady: Quotations are: Common and D., 11s. 7½d. to 11s. 9d.; 11s. 10½d. for E.; 12s. for F.; 12s. 1½d. for G.; 12s. 3d. for H.; 12s. 6d. for I.; 13s. 6d. for K.; 14s. 3d. for M.; 15s. for N.; 16s. for WG.; and 16s. 6d. for WW. Linseed oil quiet, at 27s. 6d. to 28s. per cwt., for Liverpool makes in export casks. Cottonseed oil quiet, at 32s. per cwt., for Liverpool refined in export barrels. Petroleum inactive, at 6¼d. for Russian and Roumanian, and 6⅝d. to 7⅛d. for American refined oils. Petroleum spirit steady, at 1s. 1¼d. to 1s. 3d. per gallon, for spot American deodorised. Turpentine steady, at 43s. 6d. per cwt. for spot parcels.

HULL PAINT, OIL, AND COLOUR REPORT.

Thursday.

OILS.—Markets during the week have been slack for both linseed and cottonseed oils, each having lost value considerably. The imports of linseed and cottonseed from Argentina have been considerable and well up to the average, but the demand for oils has been slow. The fall has disconcerted some speculators not altogether connected with this market, but the inconvenience has been felt here by the reduction in value. Amongst the principal imports here to date, as against the same period a year ago, have been:—Wheat, 1,910,133 qrs., against 1,981,809 qrs.; flour, 86,724 cwts., against 195,932 cwts.; linseed, 388,444 qrs., against 258,642 qrs.; rapeseed, 43,540 qrs., against 40,435 qrs.; cottonseed, Egyptian, 119,891 tons, other kinds 83,194 tons, against 99,466 tons and 72,354 tons respectively; oilcake, 16,741 tons, against 23,893 tons; hemp, 72,621 cwts., against 98,702 cwts.; olive oil, 2,621 tuns, against 2,515 tuns. Amongst the weekly imports are:—Lard, 1,728 cwts.; margarine, 4,545 cwts.; sugar, 27,694 cwts.; glucose, 479 cwts.; hides, 540 cwts.; oilcake, 1,301 tons; colours, 2,322 packages; wool, 444,923 lbs. Exports:—Oil, 10,916 cwts.; colours, 2,924 packages; chemicals, 2,816 packages. Linseed oil closes lower, 24s. 9d. spot, sellers, 23s. 9d. July-August, 22s. 7½d. September-December; boiled and refined, £1. to £1. 10s. per ton extra. Exports for the week:—6 tons Belgium, 2 Denmark, 3 Germany 21 India, 5 Norway, 4 Turkey; total, 41 tons. Refined cotton oil closes easier, at 29s. 6d. spot, naked, 29s. 1½d. July-August, 27s. 9d. September-October, 23s. 7½d. November-April; crude, ditto, spot, 28s.; casks £1. and barrels £1. 5s. per ton extra. Exports:—3 tons Germany, 3 Holland, 3 Norway; total 9 tons. Turpentine unchanged at 42s. 9d. spot; Russian easier and lower, from 22s. 6d., spot. Olive oil unchanged. Cod oil, 17s. to 19s. Rosins unchanged. Rape oil firmer in sympathy with German oil.

CAKES.—Demand seasonable but quiet, with prices ruling the same.

Digitized by Google

TYNE CHEMICAL REPORT.

THURSDAY.

Market quiet for chemicals, with a slow demand. Soda crystals unchanged, at £3. to £3. 2s. 6d. per ton, gross weights. Caustic soda, 70%, £9. 15s., and 76-77%, £10. 10s. per ton. Bleaching powder quiet, at £5. to £5. 5s. per ton. This product is now being offered for 1908 on practically same terms and conditions as this year. Sulphur scarce, at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-7%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett; do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market has been somewhat easier, and owing to scarcity of tonnage, prices for prompt loading have fallen. To-day's quotations:—Best Northumbrian steam, 14s. 3d. to 14s. 6d. per ton; second qualities, 14s. to 14s. 3d. per ton; Northumberland small coals, 10s. to 10s. 6d. per ton; best gas coals, 14s. 6d. to 15s. per ton; ditto, seconds, 13s. to 13s. 6d. per ton; Durham bunkers, 12s. 6d. to 13s. per ton; good coking coals, 13s. 6d. to 14s. per ton; household coals, 15s. to 17s. per ton; foundry coke, 24s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

Sulphate of ammonia is on a very quiet market, with only a very moderate volume passing, but the position as to value is fairly firm, at £12., f.o.b. Leith, for prompt, the same as it was a week ago. Business on the deferred delivery basis seems wholly neglected for the time. Sulphate of copper is again rather easier, and lower figures accepted. Saltcake is firm of position, at about 40s. Both naphtha and creosote remain in good demand, with more doing in forward delivery business. In the heavy chemicals the feeling is steady, with prices well maintained. Both caustic soda and bleaching powder are rather more asked after, and the call for home supplies of soda crystals has improved a little. In the section of mineral oils and paraffins (solid and liquid) the recent good feeling is retained, at the old price figures.

Chief prices current are:—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d., nett, f.o.b. Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d., nett, f.o.b. Glasgow); bleaching powder, 35-37%, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £15., and boracic acid, £24. nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal-tar and blast furnace), 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 3d.; paraffin scale, hard, 2d. to 2½d.; and soft, 2⅞d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6½d.; ordinary sorts, 6d. and 5⅞d. (open market prices for spot business) at Glasgow and other big centres; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; and 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s., Glasgow; salammoniac, first and second white, £42. and £40., less 2½% any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s., nett, Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12., prompt, f.o.b. Leith; sulphate of copper, £31. 15s., less 5% Liverpool, prompt.

New Companies.

Archangel Petroleum Company, Ltd.—Capital £50,000., in £1. shares. This company has been formed to carry on in Russia or elsewhere the business of winners and refiners of and dealers in petroleum and other mineral oils. No initial public issue. The first directors are W. Koch, F. Lane and W. R. von Ofenheim; remuneration 10% of the surplus profits after providing for 6% dividend on the issued capital, divisible. Registered office, 28, Bishopsgate-st. Within, E.C.

British Coalite Company, Ltd.—Capital £2,000,000., in 1,500,000 ordinary and 500,000 deferred ordinary shares of £1. each. This company has been formed to adopt an agreement with Coalite, Ltd., and to carry on in the United Kingdom, Europe, or elsewhere, the business of colliery proprietors, fuel and chemical manufacturers, manufacturers of and dealers in machinery and apparatus for manufacturing or increasing the illuminating or heating power of gas, spirit oil, petroleum and heat-producing agents, dealers in coke, tar, pitch, asphaltum, and other residual products. Minimum cash subscription 25% of the shares offered to the public. The number of directors is not to be less than 3 nor more than 12. Coalite, Ltd., may, for the first three years, nominate directors as under: (*a*) if the total number of directors be less than 9, two directors; (*b*) if such total number be less than 12 but not less than 9, three directors; and (*c*) if such total number exceed 12, four directors. The application for certificate of incorporation (dated 14th June) stated that no director has been appointed; but, according to the prospectus, since published, the first directors are C. Allen, J.P. (chairman Henry Bessemer and Co., Ltd.; Carlton Main Colliery Company, Ltd., near Barnsley), Bent's Green, Sheffield; Sir William H. Bailey (director of Ebbw Vale Steel, Iron and Coal Company, Ltd., and Manchester Ship Canal Company), Sale Hall, Cheshire; A. C. Cory-Wright, J.P. (director of Wm. Cory and Son, Ltd., coal factors), 52, Mark-lane, E.C.; A. G. Kitching, J.P. (director of the Metropolitan Railway Company), 7, Drapers Gardens, E.C.; Sir W. H. Preece, K.C.B., F.R.S. (director London Electric Supply Corporation, Ltd.), 8, Queen Anne's Gate, S.W.; and H. W. Pugh (Mann, George and Co., coal exporters), 23, Lime-street, E.C.; qualification £1,000.; remuneration £5,000. and 2½% of the surplus net profits after 10% has been paid on the ordinary and 12% on the deferred ordinary shares. Voting powers: one vote for each ordinary share and 3 votes for each deferred ordinary share. The directors may borrow up to the amount of the issued capital, without the sanction of a general meeting. In the event of winding-up, the available assets are to be applied firstly in repaying the capital on the ordinary shares and secondly in repaying the capital on the deferred ordinary shares, any balance being divided equally between the two classes. Registered office, 3, London Wall Buildings, E.C.

John Bibby, Sons and Co. (Garston), Ltd.—Capital £100., in £1. shares. This company has been formed to carry on the business of producers, smelters, refiners, manipulators, workers, shippers, importers, exporters, brokers and factors of and wholesale and retail dealers in copper, copper ore and other metals, ores and minerals and any products thereof, and goods made wholly or partially thereof, engineers, tube, cylinder, roller, plate, sheet, bar and wire manufacturers, tool makers, wagon, motor, locomotive and cycle builders, boiler makers, etc. No initial public issue. Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Readers will oblige by making their remittances or subscriptions by Postal or Post Office Order, crossed and payable to "Davis Bros."

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Readers are invited to forward items of intelligence, or cuttings from local newspapers, of interest to the trades concerned.

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

SOCIETY OF CHEMICAL INDUSTRY.

ANNUAL MEETING.

THE 1907 meeting of the Society of Chemical Industry, which was held at Birmingham on Wednesday last, marks a very important stage in its development. Founded in 1881 as the outcome of the activity of the members of the Faraday Club of St. Helens, the Society has now over 4,000 members in all parts of the world, and the formal announcement of the grant of a Royal Charter was very appropriately made on Wednesday by the retiring President (Mr. Eustace Carey) as a preliminary to his Presidential address.

The importance of the Society of Chemical Industry is well stated in the opening clauses of the Royal Charter. The Society was established to advance applied chemistry in all its branches; and to afford the members opportunities of interchange of ideas with respect to improvements in the various chemical industries, and for the discussion of all matters bearing upon the practice of applied chemistry, and the publication of information thereon. The Charter goes on to recite the fact that the Society now comprises amongst its members chemical manufacturers and manufacturing chemists, chemical engineers, metallurgists and metallurgical chemists, technological and consulting chemists, and other persons employed in or connected with manufacturing operations cognate to or allied with industrial chemistry, as well as professors and teachers of technology in the universities, colleges, technical institutes, and schools of the United Kingdom, and also many of the chemical and technological advisers of the various Departments of the Government. The Society's members are distributed throughout Europe, Canada, India, New South Wales, and other British Colonies and Dependencies, as well as the United States and Japan. Local Sections of the Society have been formed in the following centres:—Birmingham, Canada, Liverpool, London, Manchester, Newcastle, New England, New York, Nottingham, Scotland, Sydney (New South Wales), and Yorkshire. This recognition of the importance of the work of the Society should indeed, in the words of Sir Boverton Redwood on Wednesday, stimulate the members to higher ideals.

The annual general meeting was held on Wednesday morning, in the Medical Theatre of the Birmingham University, the President, Mr. Eustace Carey, being in the chair. Amongst others present at the opening were the Lord Mayor of Birmingham (Councillor H. J. Sayer), Sir Oliver Lodge, Sir Boverton Redwood (President-Elect of the Society), and Professor P. F. Frankland (Chairman of the Birmingham and Midland Section).

The Lord Mayor cordially welcomed the members of the Society to Birmingham, and Sir Oliver Lodge, in extending a welcome on behalf of the University, said that frequently a distinguished gathering of that kind was welcomed by universities

Digitized by Google

by the conferring of honorary degrees on some of its leaders. That would be done in many university towns, but hitherto it had not been their way in Birmingham. They had thought they would do better to acquire a little antiquity and dignity before attempting to confer it upon others. No doubt they would have to do it when their new buildings were opened, as they hoped they might be some few years hence by His Majesty the King, but until then they abstained. Sir Oliver Lodge went on to explain that the arrangements for physics and chemistry in the present University buildings were only of a temporary nature. On the new site, at the further end of Edgbaston, twenty-four acres of their buildings had risen and were rising for the applied sciences, and already they had spent about half a million in building and equipment. They believed that their arrangements for instruction in applied science were in a more expensive, and he therefore hoped more thorough, style than anywhere else in the country. They had not yet attacked the building for applied chemistry. This seemed to be such an enormous and portentous subject that he did not know how to begin or what to recommend, but perhaps the members of the Society would be able to suggest some ideas.

The President acknowledged the civic and University welcome, and formally announced that the King had been pleased to grant the Society a Royal Charter. They owed their grateful thanks to the committee of the Council who had had the matter of the Charter in hand, and especially to the chairman of that committee, Sir Boverton Redwood.

REPORT OF COUNCIL.

The report of the Council was then read. The report shows that the number of members on the register is 4,521 as compared with 4,429 at the last Annual Meeting. During the year 323 members have been elected as compared with 356 last year; the losses have been 231 as against 253. There were 42 deaths as compared with 33 last year.

The names of those who have died are:—A. C. Bealey, Joseph Bernays, Col. S. B. Bevington, Edward Blass, S. Cabot, James E. Campbell, Dr. W. H. Chandler, W. H. Cowburn, George E. Davis, T. Sebastian Davis, M. G. Dearing, Sir David Gamble, Bart., Wm. Garroway, T. A. Gerard, Wm. Glenn, F. H. Gossage, J. G. Hepburn, Prof. A. S. Herschel, J. S. Heywood, Otto Isler, E. Jenner, H. Jonker, A. E. Lewis, Thos. Macfarlane, S. L. Morison, F. J. Odling, Robert Orr, Cornelius O'Sullivan, Ira L. Pierce, Hermann Poole, Jos. T. Potts, A. Ernest Powell, W. L. Rennoldson, Benjamin Roy, John Shaw, W. B. Skerten, Oscar Unglaub, E. Cecil Wren, F. Yates, F. F. Zehetmayr, and H. B. Zimmele.

The *Journal* of the Society for 1906, together with the Supplements, numbered 1,358 pages, equal to 56.6 pages for each issue, as compared with 55.6 in 1905. During the past session 111 original papers, with discussions, have appeared in the *Journal* as compared with 78 in the previous session.

The Revenue Act of 1906, which grants facilities for the use, without payment of duty, of spirits in arts and manufactures, received the royal assent soon after last meeting; it will be remembered that the Society has taken an active part in the promotion of this Bill. Congress has passed an Act for the United States on somewhat similar lines. An exhibit of plant of all kinds for the utilisation of denatured alcohol, under the direction of Prof. Munroe, is a special feature of the Jamestown Exposition.

A Bill has been introduced into the House of Commons to amend the existing Patent laws in the direction urged upon the Government by the Council in April, 1906, when it took part in a deputation to the President of the Board of Trade.

Evidence has been given, at the instance of the Council, before the Departmental Committee appointed to consider the participation of this country in international exhibitions, and before the Committee appointed to consider what industrial diseases should be scheduled in the Workmen's Compensation Act; and evidence is about to be given before the Royal Commission on Canals and Waterways.

The Council is also represented on a joint committee of scientific and technical societies, formed for the purpose of securing for their publications postal rates not less favourable than those charged on registered newspapers.

Addresses were presented on the occasion of the Jubilees of Sir William Perkin's discovery of the first coal-tar colour, and on that of the foundation of the Société Chemique de France.

In accordance with the recommendations of the Departmental Committee on the Royal College of Science, the Council, on the invitation of the President of the Board of Education, has nominated Dr. Edward Divers, F.R.S., to represent the Society on the Governing Body of the Imperial College of Science and Technology.

His Majesty the King has been graciously pleased to grant to this Society a Royal Charter of Incorporation. By-laws under the charter are now in preparation and will be submitted for approval early next year to the members in general meeting assembled.

An invitation to meet in Newcastle-on-Tyne in 1908 will be laid before the meeting.

THE PRESIDENT'S ADDRESS.

The President then delivered his address. He said:—Since you did me the honour of electing me to be the President of our Society I have been, as is very natural, much exercised and very anxious about the subject upon which I might venture to address you to-day. I hope that the few observations upon technical training and manufacturing methods which I propose to submit to you may prove acceptable. The subject is anything but new. Nevertheless, the interest is ever new, and always increasing. The ramifications even of a manufacture so simple as that of alkali are now so numerous that but few can have an intimate practical knowledge of all the processes involved when by-products are taken into account.

At first sight it perhaps might appear that the object of the alkali manufacturer is only to dissociate sodium and chlorine, to take into partnership oxygen and carbon dioxide, and to accept in the Leblanc process the temporary services of sulphur, and in the ammonia-soda process the temporary assistance of ammonia, and to produce three or four heavy chemicals, as they are called; but that is not the modern position. The compounds of sodium and chlorine are now very numerous in themselves, and when we add that, by whichever process alkali may be produced, heat and power are required, that gas from coke ovens and other producers is now beginning to replace solid fuel, the production of ammonia and of coal-tar products comes at once into view. In addition to this, in the Leblanc branch of alkali manufacture the field is wider still, involving, besides almost all the foregoing, metallurgy for the recovery of several metals and their compounds from the pyrites used in the sulphuric acid part of that process.

The field is very wide, the industry increasingly interesting, calling now for chemical and engineering knowledge hardly thought of fifty years age. Those were the days of a rapidly growing industry. Costs were of course important, but quantity was more so. We had the world for our market, and exports increased by leaps and bounds. The good old ignorant and jealous practical man was generally in command, and his rule, not always genial, was rule of thumb. By-products by which we now make our scanty living were thrown away.

During the time that has elapsed since then the struggle for existence has continually increased in intensity. That everyone will admit, but I affirm that the scientific interest has increased in at least the same proportion, and that though technologists engaged in an old trade cannot expect the rapid money-making success of fifty or more years ago, I believe the triumphs of skill and wide scientific training will be far more brilliant in the future than in the past. As my practical experience during the past fifty years has been almost entirely connected with alkali manufacture, I shall not venture far outside the alkali field for my facts and figures.

I will endeavour very briefly to deal with the following parts of my subject:—(1.) Processes and markets; (2.) Transport facilities; (3.) Fuel; (4.) Labour conditions; (5.) Education and training of managers, chemists, foremen and men.

(1.) *Processes and Markets.*—Mr. E. K. Muspratt, in his Presidential Address in 1885, described very thoroughly the principal technical changes that had taken place in the British alkali trade up to that date; including, of course, the most interesting history of the Leblanc process from small beginnings, when, in 1823, salt was freed from the shackles of the Inland Revenue Office, through the celebrated times of invention and enterprise, inseparably associated, as we here all know, with the names of Muspratt and of Tennant; including, in fact, practically the first half of the period to which I refer.

Mr. Muspratt's review enumerated very important improvements, such as the combination of Glover and Gay Lussac towers, which reduced the consumption of nitre in sulphuric acid manufacture to one-fourth of the figure at which it had stood previously; the black-ash revolver, which both increased production and decreased cost of alkali; the Weldon manganese recovery process, which reduced the cost of bleaching

Digitized by Google

powder by £2. a ton ; the Deacon chlorine process ; and last, but not least, the introduction of the ammonia-soda process, the great and successful rival of the older Leblanc ; also the introduction of Spanish cupreous pyrites and the wet copper-extraction process. Of all these it is not necessary for me to speak. I will confine my remarks under my first head to the period subsequent to 1886.

Since 1886 there has been very material advances in the manufacture of sulphuric acid. The special conditions obtaining in Germany and the great demand there for sulphuric anhydride, consequent upon the enormous development of the German colour industry, led to some splendid researches on the contact method of oxidising sulphur dioxide into sulphuric anhydride with which the names of the Badische Anilin and Soda Fabrik, the Mannheim Chemische Verein, Haenisch and Shröder, and Dr. Messel will always be associated. Their success has been won after years of laborious and disappointing work, with how many delays due to ambiguous or apparently contradictory results perhaps only those who have assisted in working out large scale contact processes can guess. The contact process is now universally employed for the manufacture of sulphuric anhydride, and in many cases for the manufacture of the higher strengths of ordinary sulphuric acid. Whether or not in the future the contact process will replace the lead chamber method is hard to say. Before it does so, however, material advances will have to be made with respect to the life and cost for renewal of the contact material and the completeness of the reaction. We must on the other hand bear in mind that, during the last fifteen years, improvements have been effected in the old lead chamber process. This process, after the adoption of the Glover and Gay-Lussac tower combination, appeared to be a process leaving little room for improvement. The production from the sulphur employed was readily maintained at over 96%, the repairs were small, and the working cost low, the only drawback being the heavy capital expenditure. In France, I believe, first, and then in Germany and the United States, determined efforts were made to reduce this drawback ; in other words, to increase the production of sulphuric acid from a given chamber space.

The lines on which this has been effected are contained in the following sentence, which I quote from a brilliant paper read before the Liverpool Section in 1882 by the late Dr. Ferdinand Hurter :—" The reaction in the chamber produces a great quantity of heat which must be dissipated, as condensation can only proceed in proportion to the amount of heat removed ; " and Dr. Hurter proceeds to remark that " the introduction of the Sprengel water spray will probably lead to a reduction in chamber space."

Success in this direction has been attained by the use of water sprays in the leading chambers instead of the steam formerly employed to supply the necessary moisture, and by the use of intermediate towers in which the gases are cooled while passing from one chamber to another. By means of these devices the output of sulphuric acid chambers has been increased by about 40% without any material increase in the cost of manufacture. This intensified working is now very general on the Continent and in the United States, and is being slowly introduced into Great Britain.

Another very important improvement is the now well-known method of sulphur recovery, which we owe to Mr. A. M. Chance, and which is known as the Chance-Claus process, whereby the old trouble of vat waste has been finally vanquished. The Claus kiln part of the process is not yet perfect, as about 15% of the sulphur entering the kiln escapes, but considerable improvements are in sight, and it is reasonable to expect that the loss will be much reduced before long. In the meantime, Chance's beautiful process enables us to place upon the market sulphur of the highest degree of purity. With this addition, the history of the sulphur used in the Leblanc process forms a cycle of operations, commencing from the sulphur in the pyrites and passing through, successively, the conditions of sulphur dioxide and anhydride, sodium sulphate, calcium sulphide, hydrogen sulphide, and finally emerging as sulphur itself.

At one time it appeared that the rapid development of electrolysis would furnish a cheaper method of separating sodium from chlorine than a purely chemical process such as the Leblanc. Since Mr. Muspratt's paper, two very ingenious electrical processes have been worked out on a manufacturing scale, and are now in operation in large works, *viz.*, the Castner-Kellner and the Hargreaves-Bird. It seems to me, however, that there are two conditions which militate against any great development of electrolysis in soda manufacture in this country, neither of which is likely to be removed—the first is the low equivalent weight of sodium, and the second the rising price of fuel.

The later period has been less rich than the period dealt with by Mr. Muspratt in sensational technical developments, partly, no doubt, because the process is older and the more obvious improvements were already worked, but, in addition I think, very much from the fact that, the period having been one in the Leblanc industry at any rate of severe struggle, there has been less money available for expensive experiments which must always precede any great technical improvement. This period has been one of attention to details, improvement in yields and in fuel economy, and not of striking originality.

It always seems to me that, in the alkali manufacture at any rate, it is in times of prosperity and not of adversity that great advances have been made. The old text," to him that hath shall be given," has here again an application, that is, if he who hath does not wrap his talent in the napkin of sloth. The fact is that the last twenty years has, in the main, been a period of depression for the alkali and, indeed generally, for the chemical trades of this country, a fact of which individual experience has made the vast majority of us painfully aware. This period of depression, occurring simultaneously with great progress and expansion in other countries, notably in Germany and the United States, naturally turned the British mind from that condition of industrial satisfaction which, in the mid-Victorian age, coined the phrase " England the Workshop of the World," and which, in our more sober senses of to-day, we are forced to recognise as one of industrial jingoism.

The rapidity with which Britain's rivals have reduced the British industrial lead is due, I consider, in the case of the group of industries with which I am connected, to three causes, all of which have been dealt with over and over again. My only excuse for again bringing them forward is that I think they have not yet been sufficiently driven home to us. The three causes to which I refer are :—(1.) The failure of Great Britain in the nineteenth century to keep abreast of modern progress, not only in the giving of education, but, worse still, in the appreciation of it when given. (2.) The grotesque failure of the British patent law to secure for the general good that " consideration " for which alone the monopoly is granted. (3.) The loss of markets due to the protection and tariffs adopted by many of our old and important customers.

In dealing with the question of patent laws, the President referred to the agitation for reform, in which the Society has taken an important part, Mr. Ivan Levinstein, a Past-President, having been especially active. This agitation led to the appointment of a deputation from the Associated Chambers of Commerce to the President of the Board of Trade, and the case presented by this deputation was such that, in the opinion of the speaker, " no sane man could read the report without being convinced of the vital importance of reform." Reference was also made by the President to the Bill introduced by Mr. Lloyd-George, which he considers will deal effectively with the problem, and which, when passed into law, will for the first time give both British and foreign inventors a fair field and no favour.

The President next dealt with the question of loss of markets in the chemical trade, quoting statistics of the imports and exports of bleach, alkali and caustic soda for each year from 1870 to 1906. These figures show that exports of alkali and bleaching powder increased steadily up to 1880, after which they remained stationary until the early 'nineties, and then quickly fell away, while in 1900 a small but quite appreciable tonnage of imports of both alkali and bleaching powder made their appearance. The reduction in exports is shown by the following average figures.

	Soda Ash. Net exports.	Bleaching Powder. Net exports.	Caustic Soda. Exports.
	Tons.	Tons.	Tons.
Yearly average for six years ending 1885 ..	164,385	77,509	97,013
Yearly average for six years ending 1906 ..	58,211	34,732	77,509

In the opinion of the President the reductions are explained " not by our having been beaten by our foreign customers being able to manufacture more cheaply than we can, but simply by their fiscal policy, which practically excludes us from their

Digitized by Google

markets." The import duties in the various countries are as follows :—

	Bleaching Powder.	Soda Ash.	Caustic Soda.
	£ s. d.	£ s. d.	£ s. d.
Germany	0 10 2	0 15 3	1 15 7
France	1 9 0	1 13 4	2 12 10
Spain	1 4 4	1 4 4	1 16 7
Russia	7 11 9	5 19 3	9 15 1
United States	0 18 8	1 14 6	3 10 0

Dealing next with the question of transport facilities, the President observed that Mr. Muspratt in 1886 read the signs of change very accurately when he pointed to the probability that industry in this country would be hampered by inferiority of transport as compared with the facilities enjoyed by other countries who are our industrial rivals. He was glad to think, however, that the Society was taking its part in pointing out the defects in our present system, and among the many able and distinguished men who were members of the Royal Commission on Canals and Waterways was one of the original members of the Society of Chemical Industry, the Rt. Hon. Sir John Brunner, who has for years been deeply impressed with the importance of removing this handicap of inferior means of transport. The figures collected by the Internal Transport Committee of the Society show that if the cost of transport were as low in this country as in Germany or Belgium, chemical products would be cheaper to produce by 10% of the whole price. The reason for the German and Belgian superiority appeared to be twofold: First: The railway charges themselves are much lower there than here for goods in Class C. of our railway classification. The rates there are only 60% of the rates here. Second: The fact that a large part of the goods traffic both in Germany and Belgium is carried by river and canal on which the rates are materially less than by rail. The President went on to quote the evidence of Sir Cecil Hertslet, the British Consul-General in Belgium, given before the present Canal Commission, and also a table giving an analysis of the through canal toll on a considerable acid trade of the United Alkali Co. It was hopeless, he said, to compare our canals with those on the Continent, when for a journey of 77 miles the toll worked out at .82 pence per ton-mile, and the biggest boat that could be employed was one carrying an 18-ton cargo. It could only be hoped that the real hard work being performed and the genuine enthusiasm shown by the Royal Commission would be productive of practical results.

Dealing with the third division of his subject—the question of labour—which, he observed, was perhaps the most difficult of all, the President said that the last half century had been marked by an advance in the rate of wages all round, but he believed that taken on the whole this advance in the rate of wages had not been accompanied by a corresponding increase in the wages per ton of product, owing to the improvement in production and conditions of labour. Throughout the period under review there had been a succession of what had proved to be on the whole wise and salutary measures taken by the Government to improve the condition of the workers. Apart from a few questions of detail, and in rare cases of administration, he did not think that the manufacturer was inclined to grumble with respect to the working of the Factory Acts. With regard to the Workmen's Compensation Act which came into force on July 1st, it was far too early to say what the effect would be upon the industries of the country and upon workmen themselves. He considered that this Act would be a step in the direction of universal national insurance. In the meantime, especially as the tendency for large employers of labour was to take the risk themselves, he feared that the effect would be to weed out the weak and ailing, the partially crippled, and the elderly.

The great question of shorter hours of labour, in other words of a universal eight-hours day, was, through the steady continuous pressure of the Labour Unions and the now comparatively large number of Labour Members of Parliament, being slowly drawn within the range of practical politics. This might become a serious danger to any but the most successful manufacturer. While no thinking man could help sympathising with and wherever possible aiding his employees to obtain more time for themselves, more time to live in their homes with their families and their hobbies, he did not think that the excellence of the object should blind us to the practical dangers of sweeping changes. He knew from his own experience that in some departments, where the work involved heavy physical or mental strain, the change from two shifts of twelve hours to three shifts of eight hours, even though it entailed the employment each 24 hours of an extra man on the same apparatus, resulted in a reduction of the labour cost per ton of product, and better yields. He knew, on the other hand, that in many instances, the compensating increase in output or reduction of waste, was not, and could not be obtained. In a word the general labour conditions were all tending, by actual rise in wages, by restriction of hours of labour, and by the extension of the legal obligations of the employer, to raise the total labour cost of products. The same tendency was showing itself in an even more marked degree in Germany. It was within his knowledge that, in the course of the last fourteen years, the average wages of process men and labourers in two large chemical works in the Rhineland district have risen 30%, and are now practically the same as Lancashire wages. In addition, the legal charges and liabilities of the employers for insurance and compensation are greater than in this country. The result will be undoubtedly, both in this country and in Germany, that there will be a large extension in the use of labour-saving machinery, and in devices which already have been developed with so much ingenuity and skill in the United States of America.

With respect to education, the President observed that for many years past the excellence of the scientific training in the German universities and technical high schools had been held up to us as a standard for this country to emulate. No one doubted to-day that much of the development of the German chemical industry was due to the large supply of highly-trained men available in that country for technical purposes. He was glad to say, however, that with regard to higher scientific education, there had been a marked development in England of recent years in the establishment of science departments in the old universities, particularly of Cambridge, and still more in the growth of the new universities—London, Manchester, Liverpool, Birmingham, Leeds, Sheffield, and South Wales. Considerable as were the changes that had taken place in the education of the staff in manufactories since the time when he first entered the chemical trade, they were dwarfed entirely by those which had taken place in the education of the men. He had watched one or two generations of boys grow up to men in their works in Widnes, and, whatever might be the deterioration in physique and stamina produced by exhausting work and town or even slum life, there was no doubt that the boys and young men of to-day were intellectually brighter than the boys and young men of fifty years ago. Defects there had undoubtedly been in the educational organisation, defects due to lack of system, and especially to the lack of adequately trained teachers, but the final result was a distinct improvement in mental acuteness. Before leaving altogether the question of education, he would like in the strongest terms to give his support to the principles underlying Professor Meldola's recent presidential address to the Chemical Society. The work of the pure scientist was inseparably connected with every department of material progress, and every progressive country owes it to its own fair name to bear its part in the advancement of knowledge of nature's laws. The maintenance and endowment of institutions and organisations for pure research, whether physical, chemical, or physiological was in his opinion, not only the duty of the community as a whole, but pre-eminently so of those to whom technical success has brought material prosperity. We had in this country a number of institutions devoted to research, but in his opinion one and all are insufficiently supported. Dr. Mond's princely gift to the Royal Institution was an example they would like to see imitated and he felt confident that an extension of the public and private support, not only to the Royal Institution, but to the National Physical Laboratory and the Research Fund of the Chemical Society, would not only increase our prestige as an enlightened and progressive people, but from the more sordid point of view of material prosperity prove a good investment.

In concluding his address the President said :—I must now draw my desultory remarks to a close, and, in doing so, apologise for this inordinate length. I only hope that some of the points I have mentioned may, from the very facts of their having been once again raised and discussed, be brought by ever so little nearer to a satisfactory solution. In the highly complex system of modern industry in which so many agents and factors, government, capital, technical training, labour, supplies of raw materials, transport, and markets each play an important and essential part, it is no easy matter to adjudicate the respective praise or blame for prosperity or adversity. While on the whole I do not wish to acquit the manufacturer or capitalist for the share he has undoubtedly taken in delaying the progress of our

Digitized by Google

industries by the failure to demand the highest educational facilities for his staff, or even to make use of highly-trained brains when such have been available, it appears to me that want of foresight on the part of Parliament is responsible for a great portion of the disadvantages under which we have laboured.

Sir Boverton Redwood moved a vote of thanks to the President for his "eminently practical and most suggestive address." Mr. Carey had not hesitated to point out directions in which we should move with the object of placing ourselves in a better position to meet the ever-increasing keenness of competition from other nations. Undoubtedly this country occupied a position of great advantage as a centre of manufacture, but he supposed they must all admit that we had relied too much on our natural conditions. They were, he trusted, awakening to the fact that these conditions were not alone sufficient for the maintenance of commercial supremacy.—Professor Frankland, who seconded, spoke of the address as a most valuable contribution to chemical literature.—The resolution was very heartily carried.

It was decided, on the invitation of Dr. J. T. Dunn and Mr. N. H. Martin, supported by Sir Samuel Sadler (Middlesbrough), to hold the next annual meeting at Newcastle-on-Tyne.

A vote of thanks to the University of Birmingham was passed, on the motion of Dr. Edward Divers, and the company then proceeded to the Grand Hotel, where a luncheon was held.

In the afternoon a reception was given at the new University buildings at Bournbrook by the Vice-Chancellor (Alderman Beale) and the Principal (Sir Oliver Lodge). Tea was served in the Refectory, and afterwards a tour of inspection was made of those departments of the University where building operations have been completed.

On Wednesday evening a reception was held at the Council House by the Lord Mayor and Lady Mayoress (Councillor and Mrs. Sayer).

On Thursday the programme arranged for the visitors was a varied one. A number took train to Rugby for the purpose of visiting the works of the British Thomson-Houston Company in that town, leaving about mid-day for Coventry, where they inspected Messrs. Rudge-Whitworth's establishment. Another party visited the Earl of Dudley's steel works at Round Oak; others devoted their attention to the Staffordshire Steel Works, Bilston; while further contingents were shown over Messrs. Mitchells and Butlers Brewery at Cape Hill, the Birmingham Sewage Works at Saltley, the City Gas Works at Saltley, the Model Village at Bournville, and the Electric Power Station, Summer Lane. Following lunch a special saloon train conveyed a number of those otherwise engaged during the morning to Coventry, where visits were paid to the Daimler Motor Company's Works and the Automatic Machine Works, followed by a reception at the Charter House by Colonel W. F. Wyley and Mrs. Wyley. Other visitors who remained in Birmingham were entertained at the Central Fire Station by a display by the firemen, and subsequently a drive through Edgbaston brought the party to Walley Park Woods, where tea was served.

On Thursday evening a reception was given by Mr. Eustace Carey, at the Grand Hotel, followed by the Annual Banquet in the Grosvenor Room. The excursions, etc., were continued on Friday.

NITRATE OF SODA.

THE Chilian output in June, although only 673 tons larger than that in the same month last year at 152,718 tons, exceeded the estimates, and the market has consequently developed further weakness. Spot nitrate is quoted 10s. 9d. per cwt. in Hamburg, and next spring delivery is offered at 11s. 1½d., while there are sellers of prompt shipment under 9s. per quintal, f.o.b. Chili. The market is completely stagnant, buyers having withdrawn, and according to the leading Hamburg authority "it must be confessed that neither the past half year's consumption nor the Chilian output and the expected shipments justify prices sixpence per cwt. higher than those ruling a twelvemonth ago." The "export-cuota" of 45 million quintals for the current combination year has been officially confirmed, and it is expected that "only" 40 millions will be actually shipped. The latest encouragement for the market is in the shape of an inspired cablegram from Santiago, to the effect that large orders (*sic*) have been received from Indian cotton growers, who are prepared to take a considerable quantity of nitrate if the output is increased. The shipment of 786 tons to Buenos Ayres last month is also considered a good omen. In the meantime holders have been unable to dispose of four large cargoes arrived at port of call, one of these being ordered to a "secret" destination, the others to Hamburg, unsold.

THE ADULTERATION OF SODA CRYSTALS.

AT Acton Petty Sessions, on Wednesday last, before Alderman George Wright, M.C.C., and other magistrates, T. Batstone, a grocer, trading at Chiswick as Batstone's Stores, was summoned for two offences under the Merchandise Marks Act. The first offence alleged against him was for selling goods to which a false trade description, "soda," was applied; and the second was to applying to such goods a false trade description. Mr. Munby (Messrs. Munby and Nevile) appeared for Messrs. Brunner, Mond and Co. in support of the summonses. Defendant was not legally represented. He denied the offences, and elected to have the case dealt with summarily.

Mr. Munby, having briefly outlined the case, called Mr. Guyton Butler, who said he was in the employ of Messrs. Brunner, Mond and Co., and on the 7th ult. called at the shop of the defendant, 297, High-road, Chiswick, and there saw the manager, Mr. Rodd. He asked for several small articles, amongst others 7 lbs. of washing soda. While the manager was wrapping up the goods, witness handed him a written order for them, a copy of which he now produced. He explained to Mr. Rodd that he had purchased the soda with the intention of having it analysed, and asked from whom he obtained it. Mr. Rodd mentioned the London Salt Company as having supplied him with the article, and said it was purchased as a mixed soda. Witness reminded him that he had sold it to him as washing soda, and asked him if he supplied the article to his ordinary customers. He replied that if a customer asked for washing soda this article would be supplied; but that if he asked for pure soda he would be informed that he was being supplied with a mixed article. From the 7 lbs. of soda witness took four samples and placed them in separate bottles. One of these was sent to the Silvertown works of Messrs. Brunner, Mond and Co., for analysis, one was sent to the works of Messrs. Tyrer and Co., and a third was left with the defendant.

Frederick Blevins, assistant chemist to Messrs. Brunner, Mond and Co., gave similar evidence as to what happened when he accompanied the previous witness to defendant's premises.

Dr. Lamb, manager of Messrs. Brunner, Mond and Co.'s works at Silvertown, said the sample sent there for analysis contained 60% of soda and 40% of Glauber salts. Chemically, Glauber salts was sulphate of soda. It had no washing value at all, hardening the water instead of softening it. It would be exceedingly difficult for an ordinary person to distinguish Glauber salts from washing soda.

Mr. Thomas Tyrer, managing director of Thomas Tyrer and Co., Sterling Chemical Works, Stratford, E., Past-President of the Chemical Society, said the soda of commerce was carbonate of soda. Soda was a description known in the trade and to the public, and meant carbonate of soda without any admixture whatever. The price of pure soda was about three guineas per ton, that of Glauber salts about 30s. to 35s.

Mr. J. R. Davies, manager and secretary to Messrs. Western and Westall's, Limited, salt and soda merchants, said the ordinary description of soda known to commerce was crystallised carbonate of soda. He agreed with the evidence of Mr. Tyrer.

This completed the case for the prosecution.

The Chairman said the defendant was liable to a penalty of £20, or four months' imprisonment. The magistrates, however, did not wish to deal hardly with him. He would be fined £5, with three guineas costs.

CHEMICAL TRADE DEVELOPMENTS IN STAFFORDSHIRE.—It is reported that Messrs. Chance and Hunt, Ltd., of Oldbury and Wednesbury, have acquired land near Stafford, with the object of erecting a large chemical works. It is stated that the land in the vicinity has been proved to contain coal and salt.

ASSAM OIL CO.—The profits for the year were £24,652., but the directors do not, under present circumstances, feel justified in paying a dividend. They recommend that £17,500. be written off the depreciation account, leaving £7,152. to be added to the £6,710. brought forward from last year, and making the amount carried forward £13,862.

Legal Intelligence.

HIGH COURT OF JUSTICE.

CHANCERY DIVISION.

(Before Mr. Justice Warrington.)

IN RE AN APPLICATION BY COMPAGNIE INDUSTRIELLE DES PETROLES AND IN RE OPPOSITIONS BY PRICE'S PATENT CANDLE COMPANY (LIMITED), AND IN RE TRADE MARKS ACT, 1905.

The question in this case was as to the likelihood of confusion between "motorine" and "motricine" as trade marks. It was an application by way of appeal from the decision of the Comptroller of Trade Marks, who had refused to register a proposed trade mark which the applicants desired to have registered. It was at the same time an application by the applicants for rectification of the register of trade marks by excluding therefrom a trade mark of Price's Patent Candle Company (Limited) which was already on the register. Both applications were opposed by Price's Patent Candle Company.

In giving judgment on the 4th ult., Mr. Justice Warrington said that the applicants manufactured, and desired to register the word "motricine" as a trade mark for petrol spirit. That which the applicants called "motricine," and that which the opponents called "motorine," both were derived from petroleum, "motricine" being a petrol spirit highly explosive, and "motorine" being a lubricating oil from which the explosive spirit had been eliminated. Both the lubricating oil and the petrol spirit were sold, in ordinary trading, by the same class of people, and both were required for use by the same class of persons, so that in many respects the trade in regard to the oil and the trade in regard to the spirit were the same. Both the oil and the spirit were enclosed in tin canisters, so that the nature of the substance inside the tin was not ascertainable by a person who bought it until he came actually to open the tin and use it. The difference between the two substances then became apparent. In fact, one ("motricine") was a fluid liquid like water, while the other ("motorine") was a thick viscous fluid; but the difference was not apparent until actual use. Evidence had been produced as to the mode of sale and as to the use of the two articles, and the conclusion which he came to upon the evidence was that it was, to say the least, quite possible that a person who was not skilled and who should go to a shop where lubricating oil and petrol spirit were both dealt in, and who should ask to be supplied with "motorine," might instead have handed to him "motricine." That, on the evidence, was quite possible, and he came to that conclusion, not because the witnesses who had been called said that in their opinion it was so, but because upon the facts stated by them he had formed his own opinion that it was so. It was, therefore, quite possible that there might be confusion between the two terms "motorine" and "motricine." It, further, was quite possible, again to say the least, that the result of any such confusion might be actually serious, because, supposing a person who was unskilled were to open a can of "motricine" thinking it to be "motorine," as he might do, it was quite possible that some very serious disaster might happen, whether he were attempting to actually use the spirit for lubricating purposes or whether he were opening the tin under conditions which might expose the spirits to a naked light. That possibility of confusion if "motricine" were to be sold as "motorine," might thus result in serious consequences to the public and not merely to Price's Patent Candle Company. If that were so, what was the duty of the Court in this case? Three sections of the Trade Marks Act, 1905, came into consideration, the 11th, the 19th, and the 21st. Section 11 provided that "it shall not be lawful to register as a trade mark, or part of a trade mark, any matter, the use of which would by reason of its being calculated to deceive or otherwise be disentitled to protection in a Court of Justice, or would be contrary to law or morality, or any scandalous design." That section was practically the same as section 73 of the Trade Marks Act of 1883, except that in the earlier Act the restriction was confined to words calculated to deceive, and in the latter Act applied to any matter which would be disentitled to protection. Section 73 had been under the consideration of the House of Lords in the case of "Eno *v.* Dunn," and the principle on which the Court ought to deal with cases like the present seemed to be carefully expounded in that case. Having come to the conclusion of fact at which he had arrived above, he could only apply the principle of "Eno *v.* Dunn," that, if the applicants had not made out that the mark which they sought to place on the register would not, if registered, be calculated to deceive, their application ought to be refused. If it was calculated to deceive, it was not entitled to protection, and therefore was not entitled to be registered, as being disentitled under section 11. But it had been urged that the Court had a wide discretion, and that under sections 19 and 21 the Court could allow the registration under some limitation so as to avoid all possibility of deception. But his Lordship, holding that section 11 stood in applicants way, did not think section 21 ought to be applied in their avour. That last-mentioned section applied to cases coming under section 19. The result was that the decision of the Comptroller was right and the present application to register "motricine" must be refused. As to the applications to strike off the register the word "motorine" as the trade mark of the opponents, the Trade Marks Act, 1905, defined a registrable trade mark as containing or consisting of, at least, one of certain essential particulars, among them being "(4) a word or words having no direct reference to the character or quality of the goods." The word "direct" had been introduced into the Act for the first time. His Lordship did not see how "motorine" could have any direct reference to the character or quality of what it indicated. It was a trade mark for lubricating oil, and no doubt in some way denoted a reference to motors but it did not refer, least of all directly, to the character or quality of what it indicated. It was a good trade mark accordingly; but, even if it were not, the applicants' "motricine" would be open to the objection on the same ground. The result was, therefore, that the applicants failed under both heads of their claim, and their application must be refused with costs.

Reports of Companies.

SAN PAULO MATCH FACTORY, LTD.

The report for the period from April 20 to December 31, 1906, states that the purchase of the 10,000 shares of the Companhia Nacional (Brazileira) de Phosphoros de Seguranca was completed in terms of the contract with the vendors. The accounts of the Brazilian company show that the net profit for the year 1906, after making certain adjustment entries, was £18,496. Of this £1,506. was carried to depreciation account and £1,699. (10% of the balance of profit), under the statutes of that company, was placed to reserve account, the balance, £15,291., being credited to the profit and loss account. The proportion of profit from January 1 to April 19, not being available for distribution, is carried to a reserve fund, and after debiting the profit and loss account with debenture interest, sinking fund, administration and an amount on account of preliminary expenses, there remains a balance of £3,508.

WILLANS AND ROBINSON, LTD., AND REDUCED.

The company announce that the scheme for the reduction of its capital has been submitted to the High Court and has been confirmed. The Registrar certified the registration of the Order and Minute on the 25th ultimo, and the reduction is complete.

The funding certificates in respect of the arrears of preference dividend will be issued to all holders of preference shares whose names appeared on the register of members on June 25. The certificates will be issued as soon as they are ready. Shareholders' certificates will be issued as soon as they are ready.

Shareholders who desire to appoint a nominee, in lieu of taking up the funding certificate themselves, must sign the "letter of renunciation," and their nominee, who must be of full age, will also sign it, and forward it to the company by July 23, 1907, otherwise the funding certificate will be registered in holder's name.

NEW EXPLOSIVES, LTD.

The report covering the period of the first eight months' trading by the new company (from July 1, 1906, to February 27, 1907), states that the directors regret that the keen competition, which had made itself felt prior to the reorganisation of the company, still continues, and has resulted in a trading loss for the period under review of £4,004., to which has to be added £773, the cost of the formation of the new company, leaving a debit of £4,777. to carry forward.

DIVIDENDS.

The Tyee Copper Company recommend a dividend for the past year of 7½%.

MANGANESE INDUSTRY IN INDIA.

FROM the Central Provinces, the manganese mines and quarries of the Nagpur, Bhandra, and Balaghat districts, it is expected to export 200,000 tons this year. The construction of the proposed new railway will assist the industry, and the smelting of the ore locally is possible in the future. The development of the manganese industry in the Central Provinces is still rapid, but the chief obstacle to its progress is scarcity of labour. As a rule, the work is done by contract. During 1905-6, 17 mines were at work, giving an output of over 50,000 tons over the 85,000 tons extracted the preceding year; but these figures do not include the output from shallow workings. The total value of the 1905 output is valued at Rs.3,54,148.

The Government of India is investigating alleged irregularities in the granting of licenses for manganese mining in Mysore. It is the desire of the Government to prevent monopolies, and to provide that no individual or company has a greater area than 10 square miles. Already several companies working in Mysore control areas of more than one hundred square miles, and into these matters an investigation is taking place.

Since the discovery, early in 1906, of manganese ore in the Portuguese Settlement of Goa, there have been no less than some 250 applications for mining concessions sent in to the Government. So far concessions have been granted to some half-dozen concerns, covering in all about a score of mines, some of which are situated near tidal water and not many miles away from the port of Marmugao. The ore in some cases appears to be of exceptionally good quality, and the geological formations in many parts of the country appear to be highly metalliferous. As incentives to the development of the industry the restrictions concerning mining and prospecting are not onerous, and the taxes on mines and their output are at present light. The port of Marmugao has begun to attract the Mysore export trade in manganese ore, and during the twelve months November, 1905-6, some 40,500 tons were received at the port for shipment to Europe.

THE TRADE OF CRETE.

IN reporting on the Cretan trade for the first six months of 1906, Mr. Vice-Consul Wyldbare Smith states that the value of the Cretan export trade during the period January-July, 1906, was £167,038. in excess of that for the same period in 1905. This is mainly accounted for by the very large export of olives and their products, the export of olive oil amounting to 175,802 cwts., or 122,991 cwts. more than had been exported during the first half of the preceding year.

The olive and olive oil export was, during the period under review, 175,802 cwts., valued at £211,618., as against 52,811 cwts., valued at £67,801., during the first six months of 1905. This article is disposed of throughout Europe, the United Kingdom and Egypt being the most important consumers. The 1905 crop was one of the best on record, hence the large quantity exported in 1906.

CANDIA.

Mr. Acting Vice-Consul Catocherino reports that a great part of Candia olive oil (2,500 tons) was exported to the United Kingdom during 1906, and two-thirds of the whole wine crop is sent yearly to Malta by Maltese vessels.

RATHYMO.

The olive harvest was poor, but there remained a large stock from the preceding year, which was very good (about 9,000 tons), and, on account of the harvests in Italy and Spain having been poor, the price of olive oil remained high, and was highly satisfactory to the merchants and growers. The United Kingdom figures as one of the most important importers.

KINTA TIN MINES, LTD.—Registration has been made of a debenture dated June 12, 1907, to secure £7,000., charged on the company's undertaking and property, present and future, including uncalled capital, registered.

MINING IN GALICIA.—H.M. Consul at Corunna reports that great interest has arisen as regards mining in Galicia. Representatives from Great Britain and other countries have made investigations and announce the existence of iron and copper ore, all of good quality. Owing to the absence of railways in the inland districts and harbours along the coast, the difficulty of transport will be considerable.

Egyptian Notes.

IN his report on the trade and commerce of Port Said for 1906, Mr. Consul-General Cameron notes the following imports and exports :—

1,200 tons of liquid fuel, valued at £1,170.E., were deposited in the Shell Company's tanks at Port Tewfik, Suez, as against 7,581 tons in 1905.

51,517 cases of petroleum, valued at £8,322.E., were imported, and also 3,412 tons in bulk, valued at £12,161.E.

A slight decrease is again shown in the importation of indigo, the quantity imported for the year 1906 being 476 tons, valued at £117,564.E. The artificial or synthetic indigo (all of which was imported from Germany into Egypt through Alexandria) has increased from 306 tons in 1905 to 391 tons in 1906.

530 tons of cottonseed were imported from Suakin in the same period. The importation of gum from Suakin was 2,589 tons. The gum is sent to Suez for storage. It is then selected and divided, according to quality, white and red, large and small, and then re-exported according to demand.

6,393 tons of gum were exported, valued at £130,900.E., an increase of 1,578 tons in weight and £12,906.E. in value for the year 1906.

THE RESIN AND TURPENTINE INDUSTRY IN FRANCE.

ACCORDING to the British Consul at Bordeaux, the exports of resin and pitch amounted in 1906 to 568,529 cwts., a decrease of 334,929 cwts. on the previous year. The United Kingdom received 167,118 cwts., a decrease of 165,780 cwts. Prices for resin ranged during 1906 from £1. to £1. 7s. 2d. per two cwts., net, f.o.b. Bordeaux, qualities most in demand in the United Kingdom being K., M., N., W.G., W.W., and W.W. extra.

The turpentine exports amounted to 174,748 cwts., an increase on 1905 of 24,498 cwts.; the United Kingdom received 28,005 cwts., a decrease of 7,859 cwts. Prices for essence of turpentine during 1906 ranged from £3. 15s. 2d. to £4. 17s. 7d. per two cwts., net, f.o.b., Bordeaux.

Trees 70 years old, when bled "to death," can yield 1.32 gals. of resin each per annum—*i.e.*, 5.28 gals. a tree during four years tapping. An extent of forest containing 200 trees about 50 years old can produce an average yield of 88 gals. of resin a year. After deducting cost of transport and taxes, £1. 12s. 6d. per acre would remain to be divided between the resin maker and the timber owner, leaving the latter the value of the tree to be ultimately felled. This revenue can be counted on for twenty years. Many saw mills, some supplied with all modern requisites, have arisen in the Department of the Landes. Both factory and locomobile engines are furnished with special appliances for burning sawdust, pit props and firewood being the only things turned out by hand labour.

TIN PRODUCTION IN BOLIVIA.

H.M. CONSUL at La Paz reports that the amount of tin barrilla exported in 1906 was 63,848,626 lbs. Spanish. In 1905 the amount was 60,194,828 Spanish lbs.

The proportion of tin produced by the various departments was as follows :—

Department.	Quantity. Pounds Spanish.	Equivalent in Kilos.
Potosi with Uyuni, Tupiza, Colquechaca and part which is exported through the Custom house at Oruro	34,075,669	15,674,808
Oruro	25,892,342	11,910,477
La Paz	3,800,415	1,748,191
Cochabamba	80,200	36,892
Total	63,848,626	29,370,368

Our Book Shelf.

Van Nostrand's Chemical Annual, 1907. Edited by John C. Olsen, A.M., Ph.D., with the co-operation of eminent chemists. Pp. 496. London: Archibald Constable and Co., Ltd. 1907. 12s. 6d. net.

The authors have essayed to present to the busy worker, in as condensed a form as possible, the essential portion of the vast accumulation of chemical knowledge which is at present scattered through numerous works and periodicals. That they have succeeded may, we think, be granted. The work contains the ordinary tables met with in most chemical handbooks, but in addition to these there are several noticeable features. On page 10 there begins a long table of gravimetric factors and their logarithms, which to a chemist who is thoroughly conversant with logarithms will be of great assistance. The bulk of the space of the work, however, is occupied by a useful table of organic and inorganic compounds with their principal physical and chemical data. The atomic weights adopted throughout are those compiled by the International Committee on Atomic Weights, and are based on O = 16. To the English chemist the excellent tables dealing with the chemical composition and heat of combustion of coal will not be of much use, as the data refers to American fuel.

An excellent feature of the Annual is a list, commencing on page 419, of the more important articles which have been published since January 1st, 1905. This list is divided into the following chapters:—Analytical Chemistry; General Inorganic Chemistry; Industrial Chemistry; Organic Chemistry; Physical Chemistry; and Radioactivity, each of which is subdivided into sections. At the end of the book a list of the more important works which have been published since January 1st, 1905, is given. These books are classified under two heads:—English and American, and foreign books, mostly German, the latter section also containing references to the journals in which the works are reviewed.

The Annual is worthy of a better preface, and we trust that in subsequent volumes its opening sentences may be so far altered as to be at least grammatically correct.

Systematic Practical Organic Chemistry. By G. M. Norman. B.Sc., A.I.C.Sc., F.C.S. Pp. 98. London: W. B. Clive, University Tutorial Press, Ltd. 1907. 1s. 6d.

This book, the author tells us, has been written to meet the requirements of the syllabuses issued by the Board of Education for Stages I. and II. in Practical Organic Chemistry, and forms part of the Organised Science Series. The work is practically a collection of systematically arranged notes on the preparation of such compounds as are likely to be met with in the syllabus. Its production is of that order which we now expect from such a press as Messrs. Clive's.

Practical Methods of Inorganic Chemistry. By F. Mollwo Perkin, Ph.D. Pp. 155. London: Archibald Constable and Co., Ltd. 2s. 6d. net.

Preparative work in inorganic chemistry does not, in the opinion of the author, receive the attention which it deserves, and accordingly this little book is written to enable students to carry out such work and so become better acquainted with the nature of the compounds commonly met with. The preparation of the ordinary inorganic compounds is described, and there is also a chapter on special work, such as the purification of mercury, colloidal solutions, and the preparation of a few organic compounds.

New Copper Smelter at San Francisco.—The American Smelters' Securities Co. have commenced operations on their new smelting plant at San Bruno Pt., San Francisco. Plans have been prepared for the erection of buildings to cover an area of ten acres; in all 250 acres of land have been purchased. The smelter will involve an outlay of five million dollars, and it will handle annually from $10,000,000 to $20,000,000 worth of copper, base gold, and silver ores, which will come from mines all along the Pacific coast, and also California, Mexico, Nevada and South America. The new plant will only handle copper ores, and it is stated that mines near at hand producing 2% copper can be profitably worked on the completion of this smelter.

LONDON QUARTERLY INDIGO SALES.

Messrs. Millward and Co. report as follows, under date July 8th:

The third quarterly sale of the year took place to-day. Of the 720 chests declared, 70 chests have been withdrawn, leaving 650 chests to be brought forward, classified in comparison with the corresponding sale last year as follows:—

	1907.	1906.
Bengal	250 chests	384 chests
Kurpah	340 ,, ...	70 ,,
Madras	35 ,, ...	119 ,,
Figs	6 ,, ...	32 ,,
Musters, Java, &c.	19 ,, ...	5 ,,
Total ..	650 chests	610 chests

Bengal continues in extremely small supply, ordinary and medium grades being very scarce. Most of the lots submitted were good and fine, which qualities afford at present the best relative value. Kurpah comprises a better selection than for some time past, and includes some desirable lots of more than average strength. Madras and Figs are in meagre compass and are of ordinary quality.

The market during the past quarter has been steady, with a limited but regular inquiry. More business has been reported for export than for the home trade, but the latter may show more life when the direct importations from India are exhausted. Deliveries from Manchester stock have been fairly good, and the quantity now held at that port is smaller than usual. There are numerous indications that when indigo is forthcoming in larger quantities and at lower prices a revival in home trade consumption will immediately follow.

Unfortunately climatic conditions in India continue to be unfavourable, and the long sequence of bad seasons has not yet ended. The ready disposal of the last crop at satisfactory prices so restored confidence as to cause an increased area to be put under cultivation, but the weather during the last few months in the indigo growing districts has proved almost as abnormal as in this country. At the time of sowing there was too much rain, and re-sowings had to be made. Then a prevalence of hot dry winds scorched the young plants, and prevented proper development. When the rains did come they proved excessive, and the first cuttings gave disappointing results. There are, however, prospects of better second cuttings than last year, and, although the quality is not likely to be equal to last year's excellent average, the quantity may still show some increase providing no further climatic calamities ensue. Guatemala and Java are scarce and command good prices.

Deliveries, January 1st to June 30th.		Stocks in London, July 1st.	
1907.	1906.	1907.	1906.
1,533 Chests	1,634 Chests	3,059 Chests	3,232 Chests
428 Serons	451 Serons	290 Serons	628 Serons

There was a moderate attendance at the sales, but buyers acted cautiously, and only purchased to cover actual requirements. The few medium Bengals available realised relatively high prices; fine qualities are held for an advance. Of the 720 chests declared, 220 were sold and the remainder withdrawn.

Prices may be quoted practically unchanged, good Bengal being rather dearer, and undesirable Kurpah slightly easier. Present currency is:—Bengal 2s. 9d. to 4s. 6d. per lb.; Kurpah 1s. 6d. to 2s. 10d. per lb.; Madras 1s. 6d. to 2s. 6d. per lb.; Figs 1s. 4d. per lb.; Guatemala 2s. 3d. to 3s. per lb.; Java 3s. to 5s. per lb.

Cement Exports from Bordeaux.—Exports of cement from Bordeaux amounted in 1906 to 6,578 tons, an increase compared with 1905 of 5,410 tons. None was shipped to the United Kingdom. The average for the last five years stands at 1,827 tons, the average to the United Kingdom being 47 cwts.

The Omutnoi Platinum Deposit.—The *Permskya Viedomosti* says that for some time the production of platinum has been vigorously pushed in the newly discovered deposit on the River Omutnoi, on the Polevskoi estate near the Systersk Mining Works. About nine pounds of platinum are produced per week, and about 400 hands are employed at the mines. According to the Ekaterinburg press, the Perm platinum producers have been asked to send samples of platiniferous sands to the Geological Survey Department of the United States for purposes of analysis.

Parliamentary Jottings.

HOUSE OF COMMONS.

Monday, July 8.

MINERS' (EIGHT HOURS) BILL.

On Monday last, in reply to a question by Sir J. Randles, the Home Secretary (Mr. H. Gladstone) said he hoped to introduce the Miners' (Eight Hours) Bill next week.

THE GOVERNMENT TELEPHONE SYSTEM.

The Standing Committee of the House of Commons completed the Committee stage of a Bill providing for the allocation of six millions sterling for the development of the Government telephone system.

An amendment, proposing to reduce the vote to three millions, was rejected by 19 votes to 3. Mr. Buxton (Postmaster General) stated that it was not intended to borrow the whole or even half the amount at once, and in view of the fact that the purchase of the telephone companies undertaking in 1911 would give Parliament an opportunity of reviewing the whole situation, he did not think it right that the development of the Government system should be curtailed as proposed, especially as the Treasury would have full control over every item.

TRADE DISPUTES ARBITRATION.

The text was issued of a Bill presented by Mr. Cleland to promote and facilitate arbitration in trade disputes. The Bill will make it lawful for the Board of Trade, at the request of either party or a majority of the same, to make provision for the settlement of any dispute between employer and workman by arbitration, and to establish a court to be constituted of members nominated in the following manner: Two by the employer or class of employers, two by the workmen or by the different classes of workmen, and one by agreement between the parties to the dispute, or, failing agreement, by the Board of Trade, and the member so nominated shall act as chairman of the board of arbitration. If either or any of the parties to the dispute fails to appoint a member or members of the court within a fortnight of being notified by the Board of Trade, the President of the Board of Trade may make the appointment or appointments.

THE SUGAR CONVENTION.

In reply to Mr. Seaverns, Mr. Runciman said that Sir E. Grey was not in a position for the present to make any further statement on the possible withdrawal of Great Britain from the Sugar Convention. The proposal which His Majesty's Government had made was before the other Powers who were parties to the Convention, and it was not known what decision would be arrived at respecting it.

Analytical Notes.

QUARTZ APPARATUS.

The possibility of constructing vessels for chemical work from fused quartz has long been a dream of chemists. The refractory qualities of this mineral, rivalling those of platinum itself, its hardness, and resistance to acid corrosion, sufficiently entitle it to a high place in the list of desirable materials for chemical utensils.

To these must be added the unique property of practical indifference to the expanding effect of heat. So marked is this property that articles of fused silica, of considerable thickness as compared with vessels of glass and porcelain, may be heated to redness and suddenly cooled without risk of breakage.

Against these advantages there has been hitherto the drawback of high price. The labour of building up a vessel piece by piece with the costly oxy-hydrogen or oxy-acetylene flame renders impossible the cheap production of vessels in quartz, and only those to whom economy is not a consideration can provide themselves with such luxuries.

As the result of long research the Thermal Syndicate, Ltd., of Wallsend, have succeeded in manufacturing and placing on the market such articles as muffles, basins, tubes, and sheets in semi-opaque fused silica, at prices which bring them within the reach of all chemists. The industry is young, and further improvements are already in sight, and chemists may hope to see the field of usefulness for fused silica extended in the near future. Demand is bound to stimulate supply, and every encouragement should be given to an industry so important to the analytical chemist.

Continental Notes.

WHETHER or not Archimedes understood how to determine the specific gravity of solids has been a matter of some discussion, and is of interest as throwing a light upon the amount of experimental skill possessed by the ancient Greeks. According to the particulars given by Prof. E. O. von Lippmann in the *Chemiker-Zeitung* for June 19, there can, however, be little doubt that although Archimedes had no word for the conception of specific gravity, he quite understood its nature, for in the writings of Vitruvius and of various Arabian writers there are instructions given for determining this constant, and the methods have evidently been obtained from Archimedes. Moreover, the results were used to ascertain the genuineness or otherwise of electrum and gold. Not only was the specific gravity ascertained by measuring and weighing the object, but also by observing the loss of weight in water. In the same issue, E. Gerlach continues his account of the recent developments in electro-technology, giving special attention to such objects as the new electric glow-lamps with filaments made of metals such as osmium, tantalum, and tungsten. The last named especially appears to give very good results.

A. Stahler writes on the determination and separation of bismuth and mercury by the sodium phosphate method.

In the issue of June 22, Emil Sauer discusses the question of fermentative as opposed to chemical acidification in the manufacture of spirit. It is, of course, necessary to keep the wash acid during the fermentation in order to assist the action of the yeast, and also to prevent the development of foreign bacteria. The author describes the experiments and investigations he has made to ascertain the comparative value of the lactic acid process for producing this acid, and a special sulphuric acid process of his own, which is now in use in a number of factories, and is claimed to be considerably more economical than the ordinary method.

Dr. Ottomar Thiele writes suggesting the production of ethereal oils from Samoan flowers and drugs. He points out that in the Pacific islands the conditions are very favourable to the development of this industry, and that the capital outlay would not require to be very great. Such scents as Ylang-Ylang could be produced, at least in the crude state, and could be sent to Germany to be worked up. In this way the cost of transport would be saved, as also the great losses that occur in the drying and carriage of these delicate natural products. The establishment of this industry in the German colonies would help to break down the monopoly which is at present to a large extent in the hands of Americans. A method for the preparation of selenic acid from selenious acid is given by R. T. Glauser. When an aqueous solution of selenious acid is submitted to electrolysis, selenium separates at the cathode and selenic acid at the anode, and by suitably arranging the conditions it is possible very greatly to increase the proportion of selenic acid produced. The best method is to electrolyse a concentrated solution of selenious acid in concentrated nitric acid at a temperature of 50° to 80° C, with a current density of 4 to 5 amperes to the square centimetre.

In the same issue there is a description of some new forms of holders for test-tubes, thermometers, and flasks.

In the *Chemiker-Zeitung* for June 26, Dr. R. Ditmar gives an account of a series of experiments that he has carried out to ascertain the effect upon indiarubber of vulcanisation under very high air pressure. He found that under a pressure of 15 atmospheres the velocity of vulcanisation was several times as great as under one atmosphere. The elasticity and percentage of combined sulphur were also better. The only disadvantage was that the vulcanised rubber was oxidised more easily and rapidly.

In the same issue, M. R. Moffat and H. S. Spiro describe a method for colorimetrically determining the lead in water, the method depending upon the formation of a blue colour when haematoxylin is added to water containing a trace of lead.

E. Knecht gives a sensitive reaction for titanium, depending upon the decolorisation of a dilute solution of indigo or methylene blue.

A method for detecting phosphorus sesquisulphide in match-heads is described by L. Wolter. It depends upon the fact that in carbon bisulphide solution a molecule of the sesquisulphide combines directly with two atoms of iodine to form a yellow compound $P_4S_3I_2$, which can be made to separate in yellow crystals by cooling the solution to 0° C.

There is also a description of a stoneware centrifugal, provided with a circulating mechanism for the liquid. The machine is specially recommended for nitrating, and impregnating fibrous material.

SHIPPING RINGS.

AT the last sitting of the Commission appointed to inquire into the effect of the working of shipping rings on trade, Mr. Douglas Owen said that in the summer of 1904 he was requested by the Colonial Office to proceed to Johannesburg to assist, as an impartial expert, at a conference called by Lord Milner, at the instance of the trading committees of South Africa, to consider the relations between the traders and the shipowners. A South African shipping "ring" was then in operation. The most serious of the merchants' complaints, he thought, was that of giving an unfair preference to American shippers. The complaint was well founded, though it was necessary to analyse it, more especially as the traders were primarily championing the cause of the consumer, who was understood to be the principal victim of the ring. If the rates charged on the goods from England were on their own merits reasonable, it was not evident in what way the consumers, as such, were injured by a system which enabled them to buy American manufactures cheaper than English. That the system was highly prejudicial to British manufacturers was evident enough, but this did not hurt the South African consumers, as such. An impartial review of the facts made it abundantly clear that the disadvantages of the ring system, as well as its advantages, were very notable. But whereas the advantages mainly accrued to the South African traders and to the shipowners in the ring, the disadvantages fell largely on those British manufacturers whose goods had to pay a higher freight than those of their American competitors. If the system was objectionable, however, clearly the traders were themselves to blame. They lent themselves to it solely for the advantages which they expected to get, and generally did get. He suggested that the shipowners should declare that in the event of a freight war rendering it necessary for them in their own interest to carry American goods at lower rates than British goods, they should share with the British manufacturers injured any extra discount specially granted by the manufacturers in order to neutralise the saving in freight accorded to the Americans. This would be evidence of a desire of the ring not utterly to disregard the rights and well being of British manufacturers, and would also be a security that the ring would do their utmost to avoid a freight war. In his opinion the loss really suffered by the manufacturers was by no means so heavy as individual instances might lead it to be supposed, and the burden on shipowners would in consequence not be heavy. Should the shipowners accept the proposition, his opinion was, as regarded other questions, that the traders and the shipowners might well be left to settle their differences in South Africa as similar differences had been settled elsewhere.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in Smelting Ores Containing Sulphides. J. T. Carrick, 1, Baines' Buildings, Commissioner Street, Johannesburg, Transvaal, South Africa, and S. Pattison, 128, Cullinan Buildings, Johannesburg. British Patent, 22,166. October 8, 1906.

The inventors claim :—(1.) In the smelting of sulphide ores of the class specified, the process of treating matter with dilute sulphuric acid for the production of sulphuretted hydrogen, and utilising such gas as fuel in subsequent smelting. (2.) The process of treating sulphide ores of the class specified, which consists in smelting the ore to produce a matte, treating such matte with dilute sulphuric acid for the production of sulphuretted hydrogen, utilising such gas as fuel in subsequent smelting, and treating the residues resulting from the treatment of the matte for the recovery of the metals therefrom. (3.) In the smelting of sulphide ores of the class specified, the process of treating matte with dilute sulphuric acid for the production of sulphuretted hydrogen ; utilising such gas as fuel in subsequent smelting ; treating the flue gases, of which the sulphur dioxide contents have been enriched by the sulphuretted hydrogen, for the manufacture of sulphuric acid, digesting the matte with such sulphuric acid for the production of a further quantity of sulphuretted hydrogen, and utilising such gas as fuel in subsequent smelting.

Improvements in the Purification of Sulphuric Acid and the Recovery of By-products Therefrom. J. Raschen, A. E. Wareing, J. H. Shores, and the United Alkali Co., Ltd., all of 30, James Street, Liverpool. British Patent, 23,130. October 18, 1906.

The inventors observe that in the purification of sulphuric acid according to the process described in specification No. 5,151 of 1906, the reduction of arsenic compounds to the arsenious state by means of charcoal is a slow process, unless such a temperature be employed that partial disintegration of the charcoal takes place, and this not only objectionably discolours the sulphuric acid, but also causes blockages, and a further objection is that, if selenium, in any form, be present in the sulphuric acid being purified, the reaction soon ceases owing to selenium depositing on the charcoal. It is the object of the present invention to overcome these objections, whilst effecting the reduction of compounds of arsenic to the arsenious state quantitatively, or practically so. This is effected by subjecting the sulphuric acid to be purified to the combined action of hydrochloric acid and either sulphur or charcoal, a temperature being employed of preferably 100° C. or below, which does not cause disintegration of the charcoal, if that be used, and the reaction is more quickly effected than is the case when charcoal is used alone as hitherto, and moreover, when charcoal is used, the deposition of selenium is prevented, or in main part prevented, so that there is practically no hindrance to continued reduction. If it should be found that any slight deposition of selenium which may take place in prolonged working should render the charcoal less active, such deposit can be readily removed by washing with hydrochloric acid and an oxidising agent, such, for example, as a hypochlorite, or a chlorate. The use of hydrochloric acid and sulphur is only suitable for effecting the improved reduction when selenium is not present in the sulphuric acid, charcoal and hydrochloric acid being used when selenium is present.

Improvements in the Manufacture and Production of Stable Solid Zinc Hydro sulphite. J. Y. Johnson, 47, Lincoln's Inn Fields, London. (Communicated by Badische Anilin and Soda Fabrik, Ludwigshafen A/Rhein.) British Patent, 3,811. February 15 1907.

The patentee observes that in the "Wiener Monatshefte," vol. 20, page 681, is described the production of solid zinc hydrosulphite by reacting with sulphur dioxide on zinc, in the presence of alcohol. The author poured absolute alcohol (which has been distilled several times over sodium) on to granulated zinc and then passed in sulphur dioxide whilst cooling in order to prevent decomposition of the zinc salt formed. The zinc hydrosulphite is thus formed in the form of long needle-like crystals, and is unstable, as, even when in closed vessels, it evolves sulphur dioxide after a few days, whilst in the presence of the atmosphere its reducing power diminishes rapidly, and it is therefore (in common with zinc hydrosulphite which has been prepared in aqueous solution) unsuitable for use in manufactures.

The inventors have discovered that by passing a current of sulphur dioxide into a mixture of zinc dust and alcohol at a temperature above 40° C. (preferably between 60° and 75° C.) zinc hydrosulphite is obtained which possesses excellent keeping properties. In carrying out this invention, either absolute or diluted alcohol can be employed. When diluted alcohol is used, it is preferred to use such a concentration that the zinc hydrosulphite formed remains, as far as possible, undissolved. The zinc hydrosulphite is obtained in almost theoretical yield, and is in the form of large six-sided transparent leaflets, and, after drying, for instance *in vacuo*, is of excellent stability. Either ethyl alcohol, or other alcohols, such for instance as methyl-alcohol, amyl-alcohol, and glycerine, and also other liquids which, either wholly or partly, prevent the zinc hydrosulphite from going into solution can be employed in carrying out the invention.

The following is an example of how the process can be carried into effect. The parts are by weight. Allow 470 parts of sulphur dioxide to react on a mixture of 600 parts of methylated spirits, 250 parts of water and 270 parts of zinc dust, at a temperature of from 60° to 75° C., whilst stirring the mixture. A paste of crystalline zinc hydrosulphite is thereby obtained. Filter this off, and wash it with methylated spirits and dry it *in vacuo* at a temperature of from 60° to 70° C., the zinc hydrosulphite being thus obtained in the condition of dry powder.

GRAPHITE DEPOSIT IN QUEENSLAND.—It is pointed out that the demand for graphite is at present greater than can be supplied, and that adulterated materials are coming into use. Attention to the existence of an extensive deposit of this valuable material four miles from Netherby railway station, on the North coast line, Queensland, with a railage of only 30 miles to the port of Maryborough, will therefore be welcomed. This deposit holds out every inducement for an extensive and profitable manufacturing industry being opened up in Australia, as hitherto the production of clean graphite in that country has been unknown, although the mineral has been looked for in many places. The Queensland graphite plumbago mine was opened up three years ago. The development of the mine is extensive, showing a good body of the material about 30 ft. thick, with bands of other material through it. The great difficulty was to cut a road down the mountain, which has been done. The material has been shipped to various parts of the world, and is said to have given great satisfaction for all uses.

ARIZONA COPPER COMPANY, LTD.—The profits for the half year, including £11,508. brought forward, amount to £250,687. After paying preference charges the directors have resolved to pay an interim dividend of 2s. 3d., free of income tax, on the preferred and deferred shares, leaving £76,433. to be carried forward.

"MOLYBDOTT."—It is reported from Paris that M. Andre Lancien a student at the School of Medicine, at Rochefort, has discovered a substance which he calls "Molybdott." It is stated that the substance possesses the same properties as radium bromide, and that it costs only about 20f. per gramme.

BANGOR UNIVERSITY COLLEGE.—On Wednesday last, at Bangor, His Majesty the King laid the foundation of a new block of buildings for the University College of North Wales. The number of students in the first year of the College (1884) was 58. The return for 1904-5 is 328.

ANGLO-GERMAN SULPHATE.—According to the report of the Coal Distillation Company of Gelsenkirchen, last year's output was 84,912 tons of coke, 1,239 tons of sulphate of ammonia (against 1,147 tons in 1905), 2,100 tons of tar, 338 tons of pitch, 17 tons of salammoniac, and 2,273 tons of benzols. The company erected to order in England 30 coke-ovens with sulphate and tar recovery plant, and is now putting up a larger set of 60 ovens. No wonder the production of sulphate of ammonia is everywhere increasing by leaps and bounds.

THE BRITISH WESTINGHOUSE COMPANY.—On Tuesday week, Mr. Justice Neville, sitting in the Chancery Division, was asked to sanction the reduction of the capital of the British Westinghouse Electric and Manufacturing Company, Limited. The capital, said Mr. Kirby, was £3,250,000., which was obtained under the impression that the American and other patents taken over by the company would have proved of higher value than they actually did. Mr. Kirby gave details of the proposed reduction, which was £1,375,000. He acknowledged that the actual depreciation amounted to at least £1,380,000. His Lordship sanctioned the reduction applied for, but made a stipulation that the company should for six months to come use the words "and reduced" as an addendum to their designation.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, June 17, 1907.

(Rate of Exchange, $4.87½ = £1.)

Nitrate of soda is steady, but dull on spot, at $2.75. per 100 lbs., and for shipments at $2.55. Sulphate of ammonia is $3.05. per 100 lbs., and is in fair demand. Grey muriate is steady at 6½c. as to make. White muriate inclines to be more plentiful at about the same range. Lump carbonate of ammonia is firm at 7⅞c. to 8c. Lump salammoniac is unchanged at 9½c. Bleaching powders are rather dull, and range from $1.20. to $1.30 per 100 lbs. Alkali is 92½c. for light 58%, in bags, f.o.r. makers' works. Caustic remains $2.07½ for 74%, same conditions. Sulphate of copper has been reduced by the syndicate to 7½c. in round lots, which price is more or less nominal, owing to outside competition. White powdered arsenic is very dull on spot at 7½c. per lb., but firm for futures up to 7½c. Red Saxony arsenic is firm at 7½c. Calcined potash, 80-85%, is unchanged at 3¾c. to 3⅞c. per lb., and hydrated tends upwards at 4¼c. Chlorates are maintained at the syndicate price previously reported. Combination between all the makers of bichromates results in an advance of price of soda to 7½c. per lb., and potash to 8⅝c per lb. Prussiates are quite dull, and soda may now be had a 10c. per lb., with potash at 16c. Oxalic acid is slow at 8¾c. to 9c

TAR AND AMMONIA PRODUCTS.

FRIDAY.

Benzols quiet, with values given at 9d. for 90's, and 9½d. for 50-90's. Crude tar, 16s. to 20s. per ton, Thames; 1¼d. to 1⅜d. per gal., delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, London, 26s. to 26s. 6d., f.o.b.; Gas Company, 30s. 6d.; East Coast, 25s. to 25s. 6d.; West Coast, 23s. 6d. to 24s. 6d.; next year, 2s. 6d. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 11½d. to 1s.; pure, 1s. 8½d. to 1s. 9d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5½d.; 60%, 1s. 7½d. to 1s. 7⅝d.; 75%, 1s. 11¾d. to 2s.; crystals, 39-40, 5¾d.; 34-35, 5½d. Cresylic, 95%, 1s. 1½d. to 1s. 2d. Anthracene, 40 to 45 per cent A, 1½d. to 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia steady but quiet. Nearest values are: Beckton, £12. 2s. 6d. to £12. 5s.; Beckton terms, £11. 13s. 9d.; London (outside makes), £11. 17s. 6d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d. to £11. 18s. 9d.; Manchester, £11. 15s. to £11. 16s. 3d.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d.; Liverpool ordinary, 11s., and refined, 11s. 3d. Official quotations:—Cargoes, off coast or due, 10s. 11½d.; ditto for prompt shipment, 11s. 3d.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: Standard brands, £98. to £98. 5s. cash, and £90. 5s. to £90. 10s. three months. Tin: G.M. quality, £188. 10s. to £189. cash, and £180. 10s. to £181. three months; English, £190. Lead: soft foreign, July delivery, £21. 15s. to £22.; July shipment, £21. 7s. 6d.; September, £20. 12s. 6d.; English, £22. to £22. 5s. Spelter, ordinary brands, July, £24. 7s. 6d., ex ship; hard, £20. 10s. f.o.b. Antimony, £43. to £48.; ore, £10. to £10. 10s. Bismuth, 6s. 6d. Quicksilver, £6.; seconds, £6. 10s. Nickel, £175. to £185. Pig-iron closing prices:—Standard, 56s. 7½d. cash, and 56s. 10d. one month; Cleveland, 56s. 10½d. cash, and 57s. 1d. one month.

FERTILISER MATERIALS.

FRIDAY.

Although the market for manure material is quiet, prices are well maintained.

Mineral phosphates remain without change, quotations being firm for all grades in all positions.

Shippers of East Indian bone meal still maintain strong views, requiring, for shipment, £5. 2s. 6d. per ton, nett, c.i.f. terms, Liverpool. On spot £5. 7s. 6d. to £5. 12s. 6d. per ton is asked, according to quality, ex store.

Nitrate of soda is rather quiet, but quotations are steady at 11s. per cwt. for 95% and 11s. 3d. per cwt. for refined quality.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—The value of all articles of interest to this market has been declining throughout the week—cottonseed oil has declined by about 30s. ton, and linseed oil by about £2.; the market for linseed has been slow and easier, and cottonseed steady but quiet. Amongst the principal imports here to date as against the same period a year ago have been :—Wheat, 2,035,509 qrs. against 2,092,110 qrs. Flour, 88,846 cwts. against 199,033 cwts.; linseed 393,820 qrs., against 282,258 qrs.; rapeseed 40,634 qrs., against 40,485 qrs.; cottonseed, Egyptian, 119,891 tons; other kinds, 89,989 tons against 100,277 tons, and 72,816 tons; oilcake 16,996 tons, against 24,540 tons; hemp 74,926 cwts., against 99,892 cwts.; olive oil 3,082 tuns, against 2,537 tuns; tar 2,041 brls., against 1,680 brls. Amongst the weekly imports are laid 4,012 cwts.; margarine 2,846 cwts.; sugar 17,134 cwts.; hides 945 cwts.; hemp 3,077 cwts.; colours 2,084 pkgs.; wool 260,960 lbs.; oilcake 60 tons; Exports :—Oil 9,842 cwts.; colours 3,194 pkgs.; chemicals 1,986 pkgs. Linseed is quoted here for La Plata spot 42s. per q., ron passage 42s.; June July sold at 42s. 3d. New crop, December-January, 41s. 6d; linseed oil naked spot, 22s. 10½d.; July-August, 22s. 9d.; September-December, 21s. 10½d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports for the week: 1 ton Denmark, 1 Egypt, 7 France, 6 Germany, 11 India, 2 Norway, total 28 tons. Cottonseed quiet, spot £7. 16s. 3d.; October, £7. 3s. 9d.; November-January, £7.; Bombay, for parcels afloat, £5. 15s.; June-July, £5. 16s. 3d.; July-August, £5. 17s.; December-January, £5. 15s.; refined cottonseed oil lower, 28s. 1½d., spot naked; July-August, 28s. 1½d.; September-October, 27s. 2d.; November-April, 23s.; casks and barrels, £1. to £1. 10s. pet ton extra. Exports for the week: 81 tons Germany, 3 Holland, 1 Norway, total 85 tons; Turpentine weak, with business transacted below the official quotations, spot, 42s. 6d.; July-December, 43s. 6d.; January-April, 45s.; Russian in sympathy is weaker and lower business done at 21s. 6d. spot. Rosins from 11s., according to grade; olive oil firm, £34.; castor oil, unchanged; cod oil, £16. to £19.

CAKES.—Steady at a reduction all round of about 2s. 6d.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

OILS.—Palm oil quiet, sales including Grand Bassa and Dixcove on spot, £27. 10s.; hard oils, July, £28. 10s., afloat, £29.; Lagos on spot, £30. 5s.; June-July, £31., July, £30. 15s. per ton; Old Calabar, July, £30. 7s. 6d., July-August, £29. 5s.; Benin, on spot, £29. 5s.; half Jack and Grand Bassam, £29.; Saltpond, July, £28. 7s. 6d.; Accra, spot, £28. 10s., July-August, £28. 12s. 6d., early arrival, £28. 15s. Olive oil steady at £37. to £38. 10s. per tun, c.i.f., for Levant, and £37. c. and f. for Corfu. Linseed oil dull at 26s. 9d. to 27s. 6d. per cwt. for Liverpool makes in export casks. Cottonseed oil steady, at 31s. 6d. per cwt. for Liverpool refined in export barrels. Rosin well held, at 11s. 9d. for common; 11s. 10½d. for D; 11s. 10½d. for E; 12s. for F; 12s. 1½d. for G; 12s. 3d. for H; 12s. 6d. for I; 13s. 6d. for K; 14s. 3d. for M; 15s. 6d. for N; 16s. for WG; 16s. 6d. per cwt. for WW. Tallow dull at 31s. to 34s. for North American beef; South American beef, 35s., c.i.f., for June shipment, and 34s. 9d. to 34s. 10½d. for July-August; South American mutton, 34s. 4½d., c.i.f.; Petroleum quiet at 6¼d. for Russian and Roumanian, and 6¾d. to 7¾d. for American refined oils. Petroleum spirit in fair request at 1s. 0¼d. to 1s. 3d. for American deodorised on spot. Turpentine unchanged at 43s. 6d. for spot parcels.

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes are quiet at 35s. Pearl ash, 40s. per cwt. Bark in limited supply; a parcel of quillai sold in store at £2. to £20. per ton. Berries, very quiet, with Persian selling at 55s. per cwt. Logwood and fustic quietly steady. Cutch quiet, with values unchanged. Gum arabic, quiet, but in better demand at 23s. 6d. for Niger; Ghatti, No. 1. 29s. 6d. to 30s.; No. 2, 18s. c.i.f.; Senegal, 31s. f.o.b.; soft white, 45s. to 50s.; yellow, 37s. 6d. to 40s.; Trieste, 75s. Beeswax: parcels have sold at auction at £7. 10s. to £7. 11s. 3d. for Chilian; £7. for Sierra Leone; and £7. 17s. 6d. per cwt. for Peruvian. Copal: A parcel of Gold Coast copal sold in store at 42s. 6d. to 52s. per cwt.; a parcel of Brazilian sold at 55s. to 56s. per cwt. Castor oil, steady at 3 9/16d. for good seconds Calcutta on spot, and 3⅝d. for July-August shipment; first pressure French, 3⅝d. to 3¾d.; second pressure, 3 9/16d. Gambier: block quiet, at 18s. 3d. to 18s. 6d. on spot; and 19s. to 19s. 6d. for May-June, June-July, and July-August shipment. Cubes, 28s. to 28s. 6d. on spot, and 27s. 6d. for July-August shipment. Shellac, quiet at 210s. for fair free TN Orange on spot, 205s. for August, and 196s. for October shipment, June, 195s., and July 192s., c.i.f. AC Garnet, 207s. 6d. to 210s.; good and fine orange, 225s. to 240s. GAL. 187s. 6d. to 190s. Glucose: American liquid, 43%, 10s. 6d. on spot, and 8s. for June shipment; chips, 80%, 8s. 3d.; 70%, 8s. c.i.f. American powdered starch, 10s. on spot, and 9s. 6d. c.i.f. for shipment; pearl, 9s. 4½d. on spot, and 9s. c.i.f. for shipment. Cream of tartar: 98% foreign powder, 82s.; 95%, 80s. Tartaric acid: English on spot, 11¾d.; foreign, 11¼d. Citric acid: English, 2s. 0½d.; foreign, 1s. 11¼d. to 1s. 11½d.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY

To-day is the beginning of the local industrial holidays, when the works of Glasgow and district shut down for a period of from ten days to three weeks, according to the varying demands upon each. Business also comes in for some interruption, but only for two or three days at the most, offices reopening on Tuesday the 16th inst. The market in chemicals has been quieter, but prices generally keep firm, though sulphate of copper is easier. Borax and boracic acid have been advanced 20s. per ton. Sulphate of ammonia has been in no great movement for spot, and quite a blank in forward, but quotations fully hold their own at, say, £12. to £12. 1s. 3d. for prompt, f.o.b. Leith. Creosote (coal-tar and blast-furnace) remains at 2¼d. Glasgow (naked), but the feeling is strong. Paraffins, all unchanged and steady.

Chief prices current are :—Alum (in lump) £5. 5s. to £6. nett, ex quay Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s. nett, Liverpool; bicarbonate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b., Glasgow; bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37%, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16.; and boracic acid, £25., nett, Glasgow; caustic soda, white, 76%, £10. 10s.; 70-72%, £9. 15s.; 60-62%, £8. 15s.; and cream, 60-62%, £8. 15s., all nett, Liverpool; chlorate of potash, 3¼d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace) 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 3d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 1¾d. to 2¼d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6½d.; ordinary sorts, 6d. and 5¼d., open market prices for spot business at Glasgow and other big centres; ditto (lubricating) 805°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; and 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42., and £40. less 2½% any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s. nett Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d. prompt, f.o.b. Leith; sulphate of copper, £31. 5s. to £31. 7s. 6d., less 5% Liverpool, prompt.

TYNE CHEMICAL REPORT.

Market steady with a fair demand. Caustic soda is quoted at £9. 15s. for 70% and £10. 10s. per ton for 76-77%. Bleaching powder steady at £5. to £5. 5s. per ton for prompt. Soda crystals locally firm at £2. 17s. 6d. to £3. 2s. 6d. per ton gross weights. Sulphur steady at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76- 7%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett, do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6 l. per ton; nett; hyposulphite of so la, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett;

Digitized by Google

hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market firm with a good demand for export. Coke is also strong, and in request for both furnace and foundry qualities. To-day's quotations:—Best Northumbrian steam 14s. 6d. to 14s. 9d. per ton; second qualities, 14s. to 14s. 3d. per ton; Northumbrian small coals, 10s. to 10s. 3d. per ton; best gas coals, 14s. 6d. to 15s. per ton; do. seconds, 13s. to 13s. 6d. per ton; Durham bunkers, 12s. 6d. to 13s. per ton; coking coals, 13s. 6d. to 14s. per ton; household coals, 15s. to 17s. per ton; foundry coke, 24s. per ton.

New Companies.

Anglo-Saxon Petroleum Co., Ltd.—Capital £4,000,000., in £10. shares (240,000 "A" and 160,000 "B") This company has been formed to carry on the business of producers, refiners, storers, transporters, suppliers, sellers and distributers of petroleum and other oils and the products thereof, etc. No initial public issue. The number of directors is not to be less than five nor more than six. The registered holders of the A shares for the time being issued may from time to time appoint three directors, and the registered holders of the B shares for the time being issued may appoint two. The holders of the "A" shares may, subject to the consent of the holders of the "B" shares, appoint one additional director, who must be approved by the "B" shareholders at the time of his appointment. The "A" and "B" shares rank pari passu as regards capital and dividends. The directors may not, without the sanction of an extraordinary resolution, borrow in excess of 75% of the amount of the nominal capital.

Overseas Navigation Co., Ltd.—Capital, £15,000, in £10. shares. This company has been formed to adopt two agreements with J. Herron and I. Weaver, of Liverpool, trading as John Herron and Co., and to carry on the business of shipowners. No initial public issue. John Herron and Co. are the managers.

Celluloid Ltd.—Capital £37,500., in 30,000 preference shares of £1. each, and 150,000 ordinary shares of 1s. each. This company has been formed to adopt an agreement with J. Wolf, C. Bernadac and J. A. de Laugardiere, and to carry on the business of manufacturers of and dealers in celluloid and imitation ivory, bone, coral, and similar substances, etc. No initial public issue. The subscribers are to appoint the first directors; qualification £100.

Oxychlorides (1907), Ltd.—Capital £150,000, in £1. shares. This company has been formed to adopt an agreement with Oxychlorides, Ltd., of Winchester House, E.C., for the acquisition of certain properties and rights, and to carry on the business of miners, smelters, chemists, workers of any processes for the production, reduction, and making merchantable of minerals, metals and metallics products, etc. Minimum cash subscription 10% of the shares offered to the public. The first directors are to be appointed by the subscribers; qualification £500.; remuneration £200. per annum for the chairman and £150. each for the others, with 5% of the surplus net profits after 10% has been paid on the shares, divided (total remuneration not to exceed £5,000. in any year).

Safety Non-Explosive Reservoir Co., Ltd.—Capital £50,000. in £1. shares. This company has been formed to adopt an agreement with Cairn's Patents, Ltd., and C. B. Charlesworth, and to carry on the business of manufacturers of and dealers in articles and machines under the said patents, ironfounders, mechanical and electrical engineers, hardwaremen, etc. No initial public issue. The first directors are to be appointed by the subscribers; remuneration £100. each per annum.

PRICES CURRENT.

FRIDAY, July 12, 1907.

PREPARED BY MESSRS. HIGGINBOTTOM AND CO., 116, PORTLAND STREET, MANCHESTER.

The values stated are F.O.R. at makers' works, or at usual ports of shipment in U.K., unless otherwise specified. The price in different localities may vary.

		£	s.	d.
Acids :—				
Acetic, 25% and 40%	per cwt.	9/-	&	13/-
,, Glacial	,,		41/-	
Arsenic S.G. 2,000°	,,		32/-	
Fluoric	per lb.	0	0	4¾
Muriatic (Tower Salts), 30° Tw.	per bottle		1/-	
,, (Cylinder), 30° Tw.	,,	0	2	9
Nitric 80° Tw.	per ton	14	15	0
Nitrous nett	per cwt.	0	18	6
Oxalic	per lb.	0	0	4
Phosphoric, 1750°	,,	0	0	10½
Picric	,,	0	0	11
Sulphuric (fuming 70%)	per ton	6	0	0
,, (Pyrites, 168°)	,,	3	2	6
,, (,, 150°)	,,		30/-	
,, (free from arsenic, 145°)	,,		36/-	
Sulphurous (solution) S.G. 1025	,,	3	0	0
Tannic	per lb.	0	1	3
Tartaric	,,	0	0	11
Acetone	per ton	84	0	0
Arsenic, white powdered nett	,,	33	0	0
Alum, loose lump (delivered)	,,	5	12	6
Alumina Sulphate (pure)	,,	4	7	6
Aluminoferric	,,	2	12	6
Aluminium (Ingot metal 98/99%) nett	,,	200	0	0
Ammonia, Anhydrous	per lb.	0	1	1
,, .880	per ton	24	0	0
,, .920	,,	13	0	0
,, Carbonate	per lb.	0	0	3½
,, Muriate (grey)	per ton	25	0	0
,, ,, (sal-ammoniac) 1st & 2nd	per cwt.	42/-	&	40/-
,, Nitrate	per ton	36	0	0
,, Phosphate	,,	38	0	0
,, Sulphate (grey), London	,,	11	17	6
,, ,, ,, Hull	,,	11	15	0
,, ,, ,, Manchester	,,	11	15	0
Aniline Oil (pure)	per lb.	0	0	5½
Aniline Salt ,,	,,	0	0	4½
Antimony	per ton	50	0	0
,, (tartar emetic) 43/44%	per lb.	0	0	9½
,, (golden sulphide)	,,	0	1	3
Barium Chloride	per ton	7	5	0
,, Carbonate (native). 92/94%	,,	5	0	0
,, Sulphate (native levigated)	,,	45/-	to	65/-
Bisulphide of Carbon	,,	18	10	0
Bleaching Powder, 35% nett	,,	4	10	0
,, Liquor, 7%	,,	2	0	0
Chromium Acetate (powder)	per lb.	0	0	5¾
Calcium Chloride	per ton	2	10	0
China Clay (at Runcorn), in bulk	,,	20/-	to	27/6
Coal Tar Products and Dyes —				
Alizarine (artificial), 20% nett	per lb.	0	0	7
Magenta	,,	0	2	3
Anthracene, 40% A, f.o.b. London, per unit, per cwt.		1½	to	1¾
Benzol, 90's	per gallon	0	0	9
,, 50/90	,,	0	0	9½
Carbolic Acid (crude 60°)	,,	0	1	8
,, (crystallised 40°)	per lb.	0	0	5¾
,, (liquid 95/97%)	per gallon	0	1	3

LATE ADVERTISEMENT.

CHEMICAL Engineer is open to undertake Analytical and Research Work in his laboratory, and to Report on Works.—"1,144," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Readers will oblige by making their remittances or subscriptions by Postal or Post Office Order, crossed and payable to "Davis Bros."

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

CURRENT TOPICS.

THE RESEARCH STUDENT.

THE importance of scientific research work in its relation to industries generally, and its especial importance to the chemical industry in particular, have been of late so much emphasised that the extremely pertinent remarks of Professor Ayrton, in the Engineering Supplement to *The Times*, call for more than passing attention.

Professor Ayrton observes that research students should always have some idea as to what particular branch of work they intend to take up! "What is it you want to experiment on?" is often the question, and the recipient of the research scholarship replies, "I have not the slightest idea." Professor Ayrton takes a typical case. A student has finished his first year's tenure of a research scholarship. The Professor under whom he has worked is too kind to certify that he has not the necessary intuition for research work, so the scholarship is renewed, and the student is, at any rate, learning how to search for endowment, even if the funds are not being used for the endowment of research! When no more funds are available, the would-be researcher can always become a teacher—his ability to teach will, in the face of his degree and two years of so-called research, never be criticised. The question asked by the University of London, when considering the application of someone to be "recognised as a teacher," is not, "Can he teach?" but, "Has he published anything?" or, "Has he taken a degree?" Finally, having shown himself to be quite incompetent as a lecturer, he sinks into being a crammer, or a compiler of text-books, or a country farmer utterly devoid of interest in modern agricultural methods, in spite of the "capacity for original research" of his early youth. On the other hand, he may, if he possesses the faculty for making other people think him a person of real scientific intuition and attainments, rise to the exalted position of a scientific Sir Joseph Porter, M.A., D.Sc., F.R.S., when, like Gilbert's hero, he can sing, "Of text-book knowledge I acquired such a grip, that they gave me a fat research scholarship. That scholarship did so well for me, that now I am the recipient of an Honorary degree!"

Professor Ayrton goes on to deplore the wasting of endowments that exist for the discovering of men and women with real aptitude for research. The notion that research can only be undertaken after years of preliminary study has been disproved by the inventions of Pacinotti, Gramme, and Tesla; yet the University of London still believes that the truth can only be reached through mathematical gymnastics, never realising that ideas flash on people at strange moments. This, too, in spite of the results—obtained by experiment alone—of Faraday, Darwin, and Huxley. Edison congratulated himself on being no

Digitized by Google

mathematician, and Marconi disproved by trial the conventional theory of the transmission of electro-magnetic waves by sending messages between Cornwall and Newfoundland. No University training is necessary for conducting research: the greatest geniuses have followed no set line of thought or action. Research work should never be hampered by red tape, and it is absurd to give a research scholarship to one particular institution every year—as absurd as it would be to expect a commonplace Poet Laureate to produce an epoch-making poem annually, or a particular College to present every March a student worthy of being elected a Fellow of the Royal Society.

The charter of the Imperial College of Science and Technology has just been signed by His Majesty the King. The purposes of this College, as stated in the charter, are "to give the highest specialised instruction and to provide the fullest equipment for the most advanced training and research in various branches of science, especially in its application to industry." How, says Professor Ayrton, will this new Imperial College fare? Will research be interpreted as the scientific use of the imagination, or as the carrying out of stereotyped tests, the routine calibration of apparatus without any attempt to improve the apparatus tested? Will marks and degrees be aimed at, or will the students be trained to be interpreters of nature? Students must commence their researches with clear ideas as to what they are trying to find out. They must possess enough inventive faculty to know how to look for it, merely requiring a hint now and then, and a certain amount of pecuniary aid to save them from burning the chairs and tables to supply fuel for the furnace!

Professor Ayrton thinks that, though some of the governors of this Institution may be ornamental and others merely drags, the majority have the real aims of the College at heart, and will do their best to promote them.

THE NATIONALISATION OF WATER-POWER.

Another subject of interest to chemical manufacturers, though not, perhaps, of near importance to British manufacturers, was also dealt with recently in the Engineering Supplement to *The Times*. A Berlin correspondent mentions the transformation process that is being effected by the electrification of railways, and its bearing on the economic value of native sources of water-power. Up to the present this has been considerably neglected, even in Switzerland, Italy, and Norway, which are countries destitute of coal but rich in water-power.

The great firms engaged in the electrical industries are already taking steps to acquire the control of water-power for the purposes of traction and energy supply. In the search for sources of hydraulic power there is danger of this business falling into the hands of speculators, who will try and raise the prices as high as possible, and, furthermore, there seems a possibility of water rights becoming as formidable a monopoly as electric-power supply. There is a consensus of opinion in Germany—a country not rich in water-power—that the right to its use should be regarded as a Government monopoly. The Bavarian Government has recently announced its claim to all available sources of hydraulic energy in that country, the intention being to conduct experiments with the electrification of all the State Railways. An inventory is being prepared of all available water-powers, and a Commission has been appointed to consider and report on all the projects recently brought forward.

Among the more remarkable of recent schemes are those relating to the water-power of the Abz and Lake Walchen. The first of these relates to the project of the Baden Aniline and Soda Company to erect works for the recovery of nitrogen from the atmosphere. The second scheme is a project to supply power to the State Railways by utilising a fall of 600 feet between two lakes in Upper Bavaria. One engineer estimated that he could obtain upwards of 100,000 h.p. by means of a dam across the river Isar at Wallgau; this scheme has, however, been found to be impracticable. The plans of Herr Schueick, a Darmstadt engineer, are viewed with favour for the power supply from Lake Walchen. He proposes a dam at Wallgau which would raise the level of the lake 31 inches, giving 20,000 h.p.

UNIVERSITY GRADUATES IN TRADE AND INDUSTRY.

It is announced by the Council of the Birmingham University that in connection with the Faculty of Commerce an Advisory Board of business men has been formed. The Council believes that the active co-operation of such a body with the academic staff will tend to bring those who control large undertakings throughout the country into closer touch with the aims of this section of the University. The establishment of a Faculty of Commerce in the University is the first attempt in this country to systemise the preliminary teaching necessary for the higher positions of commercial and financial responsibility.

In the departmental administrations of large concerns, technical skill is so evidently called for that experts with the highest available training are employed in subordinate positions of authority; yet the country has hitherto neglected the training of general managers, who not only engage and superintend these experts, but have, at the same time, the responsibility of buying materials to the best advantage, of deciding as to the extension or replacement of plant, assuring the disposal of the output, and planning financial policy. In some cases departmental managers are thought capable of assimilating any knowledge outside their own special branch, so that, when a vacancy occurs in the post of managing director, it is filled from one of these sources, a state of affairs which it is urged frequently leads to disastrous results. It is not pretended that the training of the University will impart a knowledge which only experience can give, but it is suggested that the curriculum is such as to offer to business men assistants who are something more than raw material.

The course of study extends over three years, and embraces subjects specially selected to bring out the broader qualities necessary in men who aspire some day to fill positions of great responsibility. The new section of the University is expected to do for commerce preliminary work similar to that undertaken for the Army by the Royal Military Academy and the Royal Military College; its graduates will enter upon their careers with an intelligent understanding of the commercial and economic sides of business in general, it is submitted, and should be fitted for the highest posts in any branches of manufacture.

The Council, in appealing for support, point out that those interested in the Faculty can assist its work by (1) bringing the advantage of the training now offered to the knowledge of those, whether themselves engaged in commercial or in professional life, who intend their sons to follow a business career; (2) taking advantage of the material offered by the Faculty by filling positions in their service from among its graduates.

AN INDUSTRIAL ORDER OF COURAGE.

The recognition of exceptional courage displayed in war is rarely withheld by a nation whose traditions are so essentially war-like as our own ; but the public recognition of bravery when the circumstances are so prosaic and ordinary as those of the coalmine or the chemical works is quite another thing. That a gang of miners should voluntarily risk their lives in an attempt to release their imprisoned mates, under all the awful circumstances following an explosion in a coalmine, is a common occurrence enough ; but that such courage should be recognised at its true worth is specially gratifying to those who are acquainted with the real bravery which is far from an uncommon attribute of even the roughest of industrial workers, and it is with pleasure that we note the institution during the visit of the King to Cardiff, on Saturday last, of an Order for Courage displayed in mines and quarries. In commenting upon this, the *Manchester Guardian* observes that the conception of desert varies, or rather broadens, with the broadening of the polity. " Where the sword rules the only meritorious action is that of the warrior. There have been States where knowledge and wisdom were the better part of public virtue, but the normal course of change is to give a place, usually not a co-equal rank, along with military courage, to political skill, and then to industrial enterprise. The history of a nation is reflected in the qualities which at various periods it formally includes in public virtue. Until Saturday English Orders honoured the courage of the soldier, the skill of the statesman, the enterprise of the captain of industry, and the learning of the man of science. On Saturday they formally admitted the industrial democracy by recognising the patient toil and the self-sacrifice of the workman. The establishment of an Order for brave miners is memorable not because it supplies a means of honouring the valour of labour—that valour is beyond our honouring ; it is its own distinction,—it is memorable as a concrete pronouncement of the widening of the English conception of civic virtue."

DEGREE DAY AT LIVERPOOL UNIVERSITY.

ON Saturday last, which was " Degree Day " at the Liverpool University, honorary degrees were conferred on Mr. E. K. Muspratt, Principal Sir Oliver Lodge, Professor William Ostwald, Sir William Ramsay, and Sir H. E. Roscoe. The fact of the ceremony synchronising with the semi-jubilee of the foundation of University College added to the interest of the occasion, and the Chancellor (Lord Derby) took the opportunity of tracing the growth of the University of Liverpool from its inception.

Professor Harvey Gibson, in presenting the recipients of the degree of D.Sc., said :—" The task that devolves upon me is at once an honourable and an onerous one—honourable, inasmuch as my colleagues on Faculty and on Senate have deputed me to present to you for admission to the degree of Doctor of Science, *honoris causa*, some of the most distinguished scientific men of the day ; onerous, inasmuch as to acclaim any one of them worthily in the time allotted me in which to acclaim them all, would tax powers of analysis and rhetoric far beyond any I possess.

" Merely to mention the name of Principal Sir Oliver Lodge is enough to justify the action of the Senate in proposing to add yet another to the many honorary doctorates he already holds. Were it for no other reason, his past services to University College would entitle him to the highest honour we can confer upon him. It does not depreciate the merits of his successor to say that Lodge founded our School of Physics, and although the coping-stone was placed in position after his departure, when the George Holt Physics Laboratory was erected, he made its erection possible. Though now absent in the flesh, his spirit still hovers over it, animating and stimulating the workers within its walls. Sir Oliver is not merely a historian of pioneers, he is a pioneer himself. His investigations on Hertzian waves and on wireless telegraphy are epoch-making ; he is recognised as one of our leading experts on lightning-conductors and lightning-guards ; indeed, there are few branches of electricity, pure or applied, our knowledge of which Lodge has not substantially extended. Here in Liverpool we remember him as a brilliant teacher and a versatile author and thinker, and we congratulate the University of Birmingham in having acquired as its principal a physicist of the highest rank and a far-seeing and broad-minded administrator. Wherever chemistry is studied and taught, the names of Ostwald, of Ramsay, and of Roscoe are ranked with those of the giants of days gone by—Faraday, Cavendish, and Lavoisier.

Thirteen years ago the scientific world was startled by the announcement that our atmosphere contained a gas other than the three so familiar to every student. " The discovery of argon by Rayleigh and Ramsay recalls the discovery of the planet Neptune by Adams and Leverrier half a century before, for in both cases aberrations in the behaviour of one body led to the suspected existence and finding of another. Ramsay went further, and proved that argon itself had associated with it three other kindred and equally inert spirits, to which he gave the names of neon, krypton, and xenon. I will do no more than merely mention Sir William Ramsay's work on molecular complexes and on the molecular surface energy of liquids, but there is one other epoch-making discovery with which his name must ever be associated. To the joint labours of Becquerel, Lennard, Rontgen, and the two Curies, in the first instance, we owe our knowledge of that wonder of wonders, radium. To Ramsay we owe the discovery of the fact that radium itself decays into a gas identical with the helium locked up in the earth's crust, and determined 25 years ago by Norman Lockyer as present in enormous quantities in the atmosphere of the sun. Twenty centuries before Christ the mythical Hermes Thrismegistus and his alchemical disciples endeavoured to show that it was possible to transmute other metals into gold. Although the claims of the alchemists have not stood the critical tests of the chemistry of the twentieth century of this era, and although he has as yet failed to change the baser metals into that most coveted to-day, Ramsay has at least shown that the transmutation of elements is a scientific fact and not a vain imagining.

" I am at a loss whether to present Sir Henry Enfield Roscoe as a most distinguished scion of a most distinguished and historic Liverpool family ; as a servant of the nation in his capacity as ex-member of Parliament, and as a present or past member of numerous important Royal Commissions ; as an administrator and educationist in his capacity as ex-Vice-Chancellor of the University of London, ex-president of the British Association, and member of the Government Committee on Secondary Education, as well as the founder of the great Chemical School of Owens College, Manchester ; or as an investigator and writer of foremost rank in the domain of chemistry. I compromise, and present him in all four capacities. As the discoverer of the element vanadium, and the investigator of its properties and those of its compounds, he also has added to the number of the known chemical elements that go to make up this planet of ours. His researches on the chemical relations of hydrochloric acid and water and on tungsten and uranium have added to his renown, while his work on the relation between chemical change and the intensity and quality of light, merit for him the title of one of the " pioneers of photo-chemistry." The encyclopædic treatise known to every student as ' Roscoe and Schorlemmer ' stands pre-eminent among text-books of chemistry in this or any other language.

" As Mecca in the focus of Islam, so Leipzig is the Mecca of physical chemistry, and Ostwald is its prophet. On the occasion of Dr. Ostwald's recent visit to this city to co-operate in the opening of the Muspratt Laboratories, now presided over by one of his pupils, he styled himself the ' uncle ' of physical chemistry, and credited the great Swedish chemist, Arrhenius, with paternal relationship. The degree of consanguinity is of his own choosing, but what we stipulate for is that he be regarded as an uncle—not by marriage—but by blood. If to Arrhenius Dr. Ostwald would surrender the parentage of the ionic theory, he cannot dissociate himself from the title of being its apostle and expositor. To him also we owe the apotheosis of the phase rule—that revolutionary concept which seeks to explain the constitution of matter without invoking the Daltonian hypothesis. A disciple, as he claims to be, of the great Faraday, Professor Ostwald will rank in the history of chemistry as no mean rival to his master."

OBITUARY.

SIR WILLIAM PERKIN.

WE regret to record the death, which took place on Sunday last, of Sir William Henry Perkin, the founder of the coal-tar colour industry. Scarcely a year ago, the jubilee of Sir William Perkin's discovery was the subject of an international celebration, and the death of the famous chemist, following so soon afterwards, will be received with profound regret.

Sir William Perkin was born in London, on March 12, 1838, and was the youngest son of the late G. F. Perkin. Educated at the City of London School, he there made such progress in chemistry that soon after entering Dr. Hofmann's laboratory at the old Royal College of Chemistry, in Oxford-street, he was admitted to the research laboratory, and became one of Hofmann's assistants. The story of his life and of his epoch-making discovery is admirably told in the following interesting notes, which we reproduce from the obituary column of the *Manchester Guardian*.

"Perkin was only eighteen years of age when he discovered the mauve dye, which he proceeded before long to manufacture on a large scale. Sir William has told the story of the disappointment his father felt when he took up chemistry as a profession. His father, who was a builder, wished to make his son an architect. But his disappointment did not prevent the father from risking the capital he had accumulated by a life of industry in building and starting the small mauve works at Greenford Green. The father lived to see the undertaking succeed. The works at Greenford Green, much enlarged from their small beginnings, were sold in 1873.

"Since that time Sir William had mainly devoted himself to scientific research, especially in the artificial synthesis of organic bodies. His work on cinnamic acid has largely helped in the development of the artificial indigo industry, and his discovery of the synthesis of coumarin ranks him as a pioneer in another industry, that of artificial perfumes. The fear Sir William Perkin once expressed that technical work might interfere with or might prevent his following up his scientific researches has proved groundless. His remarkable physico-chemical inquiries show unusual courage, judgment, and resourcefulness in experiment.

"Last year the chemists of the world celebrated the jubilee of Sir William Perkin's discovery of the coal-tar colours. No more proper spot for that meeting could have been found than the Royal Institution, where Michael Faraday had discovered the hydrocarbon benzene—the parent of the coal-tar colours. Sir William was presented with his portrait, and with a bust (both are now being exhibited in the Royal Academy), and at the same time a fund for the endowment of chemical research in the name of Sir William Perkin was placed at the disposal of the Chemical Society. The Hofmann medal of the German Chemical Society was handed to Sir William by Professor Emil Fischer, of Berlin, and the Lavoisier medal of the French Chemical Society was presented by Professor Haller. The honour of knighthood was conferred on Sir William in the same year. Sir William was one of the secretaries of the Chemical Society from 1869 to 1883, and its President from 1883 to 1885. In 1886 he was elected a Fellow of the Royal Society, of which he held the Davy and the Royal medals. When Dr. Edward Schunk's beautiful laboratory was re-erected at Owen's College, to which it was bequeathed, his life-long friend and fellow worker, Sir William Perkin, opened the building, and on the same day the University of Manchester enrolled Sir William among her honorary Doctors.

"Sir William Perkin was twice married. His eldest son is Dr. W. H. Perkin, Professor of Organic Chemistry at the University of Manchester. His second son, Mr. A. G. Perkin, is a research chemist in the dyeing laboratory of the Leeds University, and his third son, Dr. Mollwo Perkin, is also a chemist.

"To tell the story of the origin of the coal-tar colour industry we reproduce a portion of the appreciation of Sir William's work published in the *Manchester Guardian* at the time of the jubilee celebration in July last year:—

"As a boy Sir W. H. Perkin was always interested in mechanical experiments, and some experiments on crystallisation turned his thoughts towards chemistry. . . . At 17 Perkin was promoted to the post of assistant in the private laboratory of Professor Hofmann. Here his duties did not leave much time for original work, so the ardent enthusiast had a laboratory fitted up at home, where he used to pursue his own researches during the evenings and the vacations. It was in this laboratory that the epoch-making discovery was actually made. The chance reading of a 'Report of the Royal College of Chemistry' published in 1849 by Hofmann, in which the artificial formation of quinine was discussed, led him to try to produce it in his laboratory at home. The account of his attempt and his discovery is given us by himself in the 'Hofmann Memorial Lecture,' delivered before the Chemical Society in 1893.

"'As a young chemist,' he says, 'I was ambitious enough to wish to work on this subject of the artificial formation of natural organic compounds. Probably from reading the above (Hofmann's) remarks on the importance of forming quinine, I began to think how it might be accomplished, and was led by the then popular additive and subtractive method to the idea that it might be formed from toluidine.' The idea was first to form allyl toluidine and then oxidise this body to quinine by means of potassium dichromate. 'No quinine was formed, but only a dirty reddish-brown precipitate. Unpromising though the result was, I was interested in the reaction, and thought it desirable to treat a more simple base in a similar manner. Aniline was selected, and its sulphate was treated with potassium dichromate. In this instance a black precipitate was obtained, and on examination this precipitate was found to contain the colouring matter since so well known as aniline purple or mauve and by a number of other names. All these experiments were made during the Easter vacation of 1856 in my rough laboratory at home. Very soon after the discovery of this colouring matter I found that it had the properties of a dye, and that it resisted the action of light remarkably well.' That was the discovery. Looked at in one way it might appear to be the result of chance, but those who have ever performed an oxidation of aniline and know the uninviting black, tarry mass which is produced can only wonder at the genius of a man who saw in such an experiment something interesting. The majority of chemists at that time would have either poured the whole down the waste pipe or got rid of the tar by boiling it with charcoal.

"Perkin believed in his experiments, and in conjunction with his father and brother he started the first works for the production of artificial dyes in 1857. The difficulties were immense. None of the three partners had ever been inside a chemical works, but perhaps this was no drawback, because the plant required was totally unlike anything in use at that time. . . . Nevertheless in six months the dye was produced on a commercial scale. Then, being the first member of a new class of dyes, it required new methods of application to the fibre. The laboratory process was found to give uneven results when used on a large scale. New methods of printing were necessary; new mordants were required. All these defects were remedied, and at length the new dye was launched successfully on its career. Its first name was aniline purple, or Tyrian purple. Afterwards it received the name of mauve. For a long time it was in great demand, but it gradually gave place to more brilliant but less fast colours. Its last use was for the mauve-coloured penny postage stamps of the last reign."

DR. AUGUST DUPRÉ.

The death took place on Monday, of Dr. August Dupré, Chemical Adviser to the Explosives Department of the Home Office since 1873. Dr. Dupré, who was a Fellow of the Royal Society, was born at Mainz, in Germany, in 1835, and was educated at Darmstadt, Giessen, and Heidelberg. In 1864 he became a lecturer on chemistry at Westminster Hospital School. In 1871 he was appointed Chemical Referee to the Medical Department of the Local Government Board.

CURRANT ALCOHOL IN GREECE.—A company has been formed to produce alcohol from the currants obtained by the Government under the retention-tax. The output of the company was as follows:—On June 1, 1906, the deposits contained 156¾ tons of alcohol or 96 to 97°. From June to December, 1906, 357 tons were produced, of which 335 tons were exported. During the same period, 122¾ tons were sold for lighting and heating purposes and 55¾ tons were sold to local merchants. The price of this alcohol from June to November averaged 30 to 32fr. per 100 kilos. (1 cwt. 3 qrs. 24.7 lbs.), f.o.b. Piræus, and from November to January 38fr. cash, without discount. The expected production for 1907 is 5,419 tons at 96 to 97°, of which 2,956 tons will be probably consumed in lighting, heating and in motive power, the remaining 2,463 tons being reserved for exportation. During 1907 the company expects to produce 1,970 tons at another works.

"COALITE"-"CARBO."

[FROM A CORRESPONDENT.]

THE writer cannot claim to be a chemist, but at the same time he has experimented with coal for the purpose of improving the mechanical strength—chiefly for blast furnace purposes—and also with the view of eliminating, or at any rate materially reducing, the sulphur contents. As far back as 1870 a number of experiments were made with the object of improving the coke produced from Cumberland and North Lancashire coals, and, although upon a small scale, both the mechanical and chemical conditions were considerably benefited.

The results under practical every-day burning in the then bee-hive ovens were uncertain and not satisfactory. Special forms of ovens were made during the experiments, and salt and slaked lime—milk of lime—mixed in varying proportions with crushed coal. During the experiments, owing to inattention of workmen, one of the ovens was allowed to get to a much lower temperature than the other two—there were three in all—the result being that the coke produced in the lowest and slowest temperature was found to be practically smokeless when burnt in the ordinary house fire.

There was no idea then of attempting to procure a smokeless fuel, and it was due only to the remark of a servant girl that attention was directed to the fact that the lowest temperature coke, when used in the household fire, caused less cleaning, that the experimenters obtained another idea, distinct from the one they had in view. The analysis of the semi-coke fuel is practically identical with the "Coalite" and "Carbo" now claimed as smokeless. Patents were applied for and granted, but not having the specifications or numbers at hand at the moment, the writer cannot quote the particulars. Suffice it to say that no practical results came about, although many well-known colliery owners and ironmasters had the matter put before them. At that time the North of England coal, coke, iron, and steel trades were in the hands of men who had little scientific knowledge, and who were more backward in recognising any attempt to improve or to experiment than is now the case—which is saying much. So far as can yet be gathered (without the complete specifications, which are withheld from the public) and which seems *prima facie* suggestive at least of nervousness on the part of the patentee and capitalists chiefly interested in "Coalite"—there is absolutely no difference in any way, either mechanically or chemically, between "Coalite" and "Carbo" and the slow combustion low-temperature semi-coke produced in 1870, from Cumberland and North Lancashire coal, of by no means superior quality!

The probability is that, had "Coalite" been offered to the public in 1870, it would have died a natural death, as did the improved coke then produced. The Patent Office records show many specifications in the direction of "Coalite," but until the "Coalite" specification is open to public inspection comparisons must be deferred.

So far as can be gathered, "Coalite" is neither more nor less than semi-coke, or half-cooked coal. The chemist and geologist can inform us that anthracite and the natural smokeless coal of Wales were produced under conditions materially differing from other coalfields. It is not at all improbable that the anthracites and smokeless coal owe their conditions largely to natural earth pressure, which would produce and conduce to slow heat—to a condition of carbonisation differing entirely from the coalfields of the east coast, the Midlands, and Lancashire. The elimination of the heavy hydrocarbons was by some natural process evolved; or it may be there was less natural "secretion" of the hydrocarbons. We are, it seems, about to be offered a half-cooked coal in place of the raw material, which, so far, is about all we can confidently state; how far the Metropolis will benefit from the burning of "Coalite" and "Carbo" remains to be seen. The scheme has been influentially placed before the public, but certainly there would have been greater confidence, and grounds for greater hope that the smoke nuisance would be "scotched," if not killed, had the complete specifications been boldly made public.

PRESENTATION TO MR. A. M. CHANCE.—Mr. A. M. Chance, the chairman of the directors of Messrs. Chance and Hunt (Limited), of the Oldbury Alkali Works, was the recipient, on June 28th, of two handsome presents from the directors, staff, and workpeople upon the occasion of his recent marriage.

THE FARADAY SOCIETY.

AT the thirtieth ordinary meeting of the Faraday Society, a general discussion on "Hydrates in Solution," took place. Professor S. P. U. Pickering, F.R.S., was in the chair.

After some preliminary remarks by the Chairman, the discussion was opened by Dr. T. Martin Lowry, who read a paper on "The Thermo-Chemistry of Electrolytes in Relation to the Hydrate Theory of Ionisation," by Mr. W. R. Bousfield, M.A., K.C., and himself.

(1.) The process of ionisation of a neutral salt in aqueous solution "*is usually attended with a development of heat*" (Nernst, *Theoretical Chemistry*, 1904, 659), *e.g.*, $KCl \longrightarrow \overset{+}{K} + \overset{-}{Cl} + 250$ cal. (Arrhenius, *Zeit. Phys. Chem.*, 1889, 4. 106). It is pointed out that the decomposition of potassium chloride into molecular potassium and molecular chlorine involves an absorption of 105,600 cal., and that a further absorption must accompany the decomposition of the molecules into atoms. The electrification of the atoms is also probably an endothermic action, and the change represented by the above equation, so far from involving the liberation of 250 cal., must actually involve the absorption of more than 100,000 cal. The process of ionisation must therefore involve some powerful exothermic action not shown in the ordinary scheme, and it is suggested that this is supplied by the combination of the charged atoms or "ionic nuclei" with the solvent to form hydrated ions. (2.) A scheme is given whereby the work done in charging the ions, or in separating ions already charged, may be calculated on the assumption that the ions behave as charged conductors immersed in a fluid dielectric. The values deduced for the energy of electrification or of separation range from about 1,000 to 8,000 cals. per equivalent. (3.) It is pointed out that according to the theory of electrolytic dissociation the heat of formation of a salt in dilute solution is the sum of the heats of formation of the ions. Values are deduced for the separate ionic heats of formation, and a table is given showing with what remarkable accuracy the additive law holds good; this additive relationship, which does not appear in the heats of formation of the solid salts, affords important evidence in favour of the view that the ions exist independently in dilute solutions. (4.) The majority of the heats of formation of the ions are large positive quantities. The energy liberated during the process of ionising an element cannot be due to the disruption of the molecules of the element into atoms, nor to the electrification of these atoms. Both of the above processes appear to be endothermic, and it is again necessary, in order to explain the thermochemical data, to postulate that ionisation is accompanied by some exothermic action not indicated in the symbols—

$$\frac{K_x}{x} \longrightarrow \overset{+}{K} \text{ or } \frac{Cl_2}{2} \longrightarrow \overset{-}{Cl}.$$

This exothermic action is supplied by the combination of the ionic nucleus with the solvent.

Dr. James C. Philip, M.A., Ph.D., D.Sc., read a paper entitled "Influence of Non-Electrolytes and Electrolytes on the Solubility of Gases in Water. The Question of Hydrates in Solution." The author supported the view according to which the diminished power of a solution to dissolve hydrogen and oxygen as compared with pure water is due mainly to the hydration of the solute and the consequent diminution of the "free" solvent. In determining the extent to which any given solute is hydrated, it is first supposed that the standard absorbing volume is, not 1 litre of the solution, but that volume of the solution which contains 1,000 grammes of the pure solvent. In this way values of the average molecular hydration for a number of common salts are obtained. It is found that the average molecular hydration increases with the dilution of the salt solution, and decreases for a given salt solution as the temperature rises.

Dr. George Senter read a paper on "Hydrates in Solution: Discussion of Methods Suggested for Determining Degree of Hydration." It is pointed out in the paper that recent attempts to account for the properties of aqueous solution on the basis of association alone have not only proved inadequate to afford a quantitative representation of the facts, but in some respects do not appear to be even in qualitative agreement with experiment. In forming an opinion as to the relative trustworthiness of different methods which have been suggested for determining the degree of hydration, regard must be had to the following considerations: (1.) Other things being equal, statical methods are more reliable than dynamical ones; (2.) the law of mass action requires that for salts the degree of hydration must increase with dilution

Digitized by Google

up to a point beyond which it remains practically constant on further dilution; (3.) if, as is usually the case, hydration is associated with evolution of heat, the complexity of the hydrates must decrease with rise of temperature. All the different methods indicate that the degree of hydration varies with the atomic weight; for example, in the case of the chlorides of the alkalis, the hydration decreaseswith increasing atomic weight of the alkali metals. From a quantitative point of view our knowledge of hydration is much less satisfactory, and the results so far obtained must be regarded as of a preliminary character.

A paper communicated by Dr. Alex. Findlay on "The Stability of Hydrates as Indicated by Equilibrium Curves" was read in abstract by the Secretary.

From a study of the freezing-point curves of concentrated aqueous solutions conclusions have been drawn, more especially by Biltz and by H. C. Jones, with regard to the existence of hydrates in solution. While the qualitative correctness of the conclusions may be accepted, grave doubts arise as to the correctness of the quantitative formulæ assigned by Jones to hydrates of different substances. These doubts are due not only to the fact that the conclusions as to hydration were reached (in so far as the freezing-point measurements are concerned) by means of an unjustifiable extension of van't Hoff—Raoult law, but also to the fact that certain factors, *e.g.*, heat of dilution, were not taken into account. While the study of the equilibrium curve of solutions in contact with ice as solid phase (the freezing-point curve) may, on the basis of certain assumptions, give an indication of the "degree of hydration" of the solute, it cannot enable us to decide as to the particular hydrates present, nor the extent to which these hydrates are dissociated chemically. On the other hand, some insight into the question of the stability of hydrates can be obtained from the study of the equilibrium curves of solutions in contact with the hydrates as solid phase, *i.e.*, what are frequently called solubility curves. When a compound of two components is capable of existing in contact with solution of the same composition as itself, *i.e.*, when it possesses a definite melting point, the equilibrium curve of the two-component system will exhibit an intermediate curve, which gives the conditions under which the solid compound can exist in contact with the liquid solution, or homogeneous mixture of the two components. When the compound undergoes chemical dissociation at the temperature of the melting-point, it is found that the equilibrium curve has a rounded summit, and the greater the degree of dissociation the flatter is the summit of the curve. Conversely the sharper the summit of the curve the less the degree of dissociation. From the appearance of the curve alone, then, some idea of the stability of the compound can be obtained. If, now, we regard the presence of the products of dissociation as causing a lowering of the freezing-point of the pure compound, and if we regard the lowering produced to be in accordance with the van't Hoff—Raoult law, then, from a knowledge of the molecular depression of the compound, it is possible to calculate the course of the freezing-point curve of the compound for different degrees of dissociation. The experimentally determined equilibrium curve is compared with the curves so obtained, and thus an approximate knowledge obtained of the degree of dissociation of the compound. It must be pointed out that this method of determining the degree of dissociation is only an approximate one, for it depends on various assumptions which cannot be regarded as being more than approximately fulfilled. The chief of these assumptions are: (1) the validity of the van't Hoff—Raoult law, (2) the validity of the law of mass action in concentrated solution, (3) the degree of dissociation is independent of the temperature. So far calculations have been carried out only in the case of organic binary compounds; but the method can also be applied to the case of salt hydrates, although in this case the above assumptions are less likely to be fulfilled.

Professor W. A. Tilden, F.R.S., referred to the fact that in crystals it appeared to be the metal only which detained the water of crystallisation. In many cases, such as that of ammonia dissolved in water, where ammonia as such was also present, the hydrate theory could not be adopted as it stood. There was, in fact, no single theory at present able to explain all the phenomena observed.—Mr. Caldwell criticised the various methods used for measuring hydration. In the experiments of Jones, for example, whose method was open to objection, many of the results did not follow what would be expected from the law of mass action. Philip assumed that the dissolution of a gas was mechanical and that of a salt chemical. If that were true a gas of small molecular weight, such as helium, should be readily soluble.—Mr. W. A. Davis said that there were many cases of solution, *e.g.*, in dyeing, which were covered by neither the ionic nor the hydration theory, but in which the process was purely mechanical.—Mr. Fenton said that it was not always very clear what was meant by a hydrate. The methods hitherto employed for studying hydrates were chiefly physical, and the results obtained were capable of many interpretations. The problem should be studied in such a way that specific chemical properties were obtained.

In reply to Dr. H. Borns, Dr. Lowry said he imagined ionisation to be the result of the separate hydration of the ionic constituents of the molecule.

The Chairman thought that the agreement between the heat of formation of a salt in dilute solution and the sum of the separate heats of formation of the ions shown to exist by Mr. Bousfield and Dr. Lowry proved nothing, as the proof involved reasoning in a circle.—In reply, the authors explained that the agreement proved these properties of the ions to be additive, and so gave further support to the dissociation hypothesis.

Continental Notes.

THE use of granular conducting material for heating vessels electrically is finding much favour, both in the laboratory and in the works for small-scale operations, and a short paper by J. Bronn in the *Electrochemische Zeitschrift* for May, in which he discusses the material "Kryptol," will therefore be found interesting.

Other papers in this journal deal with the metallurgy of tin and calcium.

In the *Zeitschrift für Chemische Apparatenkunde* is appearing a long paper by G. Jacob, in which he describes the various calorimeters that have been devised for the determination of the heating power of coal, and the subsidiary appliances that are used in connection with them. Instalments of the work will be found in the issues of June 1, June 15, and July 1.

The issue of June 1 also contains a description of an automatic measuring apparatus for acids, alcohol, and other liquids that must not be exposed to air more than can be avoided. C. Hoffmeister gives an account of an apparatus for extracting solid materials at high temperatures with two immiscible solvents of different specific gravities.

In the issue of June 15, an illustrated account is given of a respirator provided with a supply of liquid air. The reservoir for the air is made in the shape of a knapsack, which is carried by means of two straps that pass over the shoulders; it consists of two parts, the air-container proper, which is next the back, and a breathing bag in two compartments, made of air-tight material. The air-container is filled with ignited asbestos wool, and has a capacity of about 3½ litres of liquid air, which is sufficient to last about two hours. Two flexible tubes connect the face mask with the reservoir; one for the fresh air and one for the expired air. The latter is connected with a tube that passes diagonally through the space for liquid air, so that its heat causes the air to evaporate. In consequence of this arrangement the supply of air automatically adjusts itself. The reliability of the appliance is greatly increased by the fact that there are no valves in it. The expired air is constantly driven out by the fresh supply. It is stated that this respirator, which goes under the name of the "Aerolith," is in use in Westphalian, Belgian, and English coal mines, and has also been adopted by the London fire brigade.

In the issue of July 1, G. de Voldere describes a number of improvements in the Hempel apparatus for gas analysis.

An ingenious pressure regulator for waste steam, made by a firm in Stuttgart, is also described. This allows part of the steam to escape into the air when there is a plentiful supply, but when there is but little it is all caused to pass through the plant where it is to be further utilised, and if it fails altogether, a supply of live steam is automatically turned on. There is also an account of a furnace for burning gypsum.

Reference was made in these "Notes" two weeks ago to the liability of ether to become ignited by means of electric sparks generated by the passage of the liquid through tubes. A further report upon this subject will be found in *Die Chemische Industrie* for July 1, from the pen of Prof. M. Richter, who has made a special study of the subject. That ether may easily become electrified is readily shown by agitating a piece of mohair in it and testing with an electroscope. When tested in this way it is

Digitized by Google

found that the ether becomes more highly charged the lower its specific gravity, because the presence of alcohol and water in it causes it to conduct the electricity better. In the case of benzine it has been found possible to entirely prevent danger of this sort by adding 0.01% of magnesium oleate, which makes the liquid conduct sufficiently well. This is not practicable in the case of ether, because the oleate is insoluble, and the addition of this or other matter would make the ether useless for many purposes. The only means that can be adopted, therefore is to connect all parts of the plant to earth. In the case of funnels used for filling carboys or other vessels made of non-conducting material it has been recommended to earth them by means of a chain. But the author does not consider this a good method, as the workman may omit to adopt this precaution; he thinks it better to use funnels also made of non-conducting material, such as glass or stoneware. Carbon bisulphide is an even more dangerous liquid as regards spontaneous electrical ignition than ether, as it readily becomes charged up to more than 10,000 volts. As magnesium oleate is insoluble in this liquid also, it is necessary to adopt the same precautions as in the case of ether.

Indian Notes.

RETAIL price of phosphatic manures is Rs. 1.0 per lb., and gennine guano 6 annas per lb.

In several indigo districts the crops have suffered from the heat, caterpillars, and want of rain.

Cottonseed meal is used as a fertiliser, and it is proposed to exploit this refuse in a practical manner.

The East Indian Railway Company are obtaining a chemist from England for their colliery department; already the Company have an analytical chemist for their workshops and foundries.

Prospecting licenses are being granted in different districts. The Burma Government has issued a mineral prospecting licence over 3,200 acres in the Karen Hills, near Toungoo, known to produce silver and lead.

Salt production in the Punjab during the year 1905-6 was from the Cis-Indus and Kalabagh mines of the Salt Range, which issued 2,590,000 maunds of salt, of which 2,153,000 were from the Khewrah depot; the Mandi mines issued 98,500 maunds, and the Sultanpur works 93,000 maunds.

The question of the standardisation of fertilisers sold in India is one of importance, and is to be considered by the authorities. In Southern India a large collection of samples of mixed, or "patent" fertilisers, and of ordinary fertilisers such as oil-cakes, bone-meals, sulphate of potash, etc., have been obtained and are to be analysed.

India's loss, by the export of raw metalliferous ores, is another country's gain. Thus chromite, a mineral which is now being mined regularly in Baloochistan, at 23s. per ton, fetches treble that sum at American or European ports. This is due to the rudimentary conditions in which the metallurgical industries of India now find themselves.

The values of the imports into India during the month of April (the first month of the financial year), compared with the corresponding month last year, are:—In 1906: Chemicals, dyeing and tanning materials, etc., Rs.22,62,654, and mineral oils Rs.14,63,971. In 1907: Chemicals, dyeing and tanning materials, etc., Rs.32,33,835, and mineral oils Rs.26,46,379. Whilst the values of exports from India during the month of April in each year are:—1906: Saltpetre, indigo, chemicals, etc., Rs.91,49,278, vegetable oils Rs.5,10,947, and manganese ore Rs.7,33,278.: In 1907 Saltpetre, indigo, chemicals, etc., Rs.1,00,02,211, vegetable oils Rs.10,20,719, and manganese ore Rs.10,58,304. Both imports and exports show a marked increase during April of the present year, over the same month last year.

POTASH SALTS.—The admission of the Sollstedt and Deutsch Kali Werke (referred to in our issue of 29th ult.) increases to 37 the number of participants in the German Potash Syndicate. At the beginning of 1902 there were only 20 members, the increase thus being 17 within five years. The "quotas"—ranging from 61.18 thousandths in the case of the Prussian Fiscal Works to 15.60 thousandths in that of the Heldburg Company—have already been considerably cut down, and the process will be continued as the large number of new mines in course of construction reach the productive stage. The fall in potash shares caused by this prospective curtailment has been intensified by the recent falling-off in the Syndicate's sales.

RUSSIAN GOLD AND PLATINUM PRODUCTION.

THE *Viestnik Finanssoff* gives the total production of gold in the Urals in 1906 at 496 poods, and of platinum at 352 poods. The gold production shows a steady decline since 1902, when the production was 534 poods, and the platinum return is the largest since 1903, when it was 366 poods. It was 374 poods in 1902. The platinum mines belonging to Count P. P. Schouvaloff's successors for the first four months of the current year (1907) produced 7 poods, 7 pounds 45 solotniks 52 dolie of platinum against 6 poods 38 pounds 15 solotniks 35 dolie in the corresponding period of 1906. On the other hand, at the mines of Prince S. S. Abemilyk-Lassarieff during the period named the only work done has been preparatory, and such platinum as has been got in the time has been delivered by outsiders and in very small quantities.

The *Permskya Viedomosti* states that for some time the production of platinum has been vigorously pushed in the newly discovered deposit on the River Omutnoi, on the Polevskoi estate near the Systersk Mining Works. About nine pounds of platinum are produced per week, and about 400 hands are employed at the mines. According to the Ekaterinburg press, the Perm platinum producers have been asked to send samples of platiniferous sands to the Geological Survey Department of the United States for purposes of analysis.

The *Torg. Prom. Gazeta* gives some supplementary statistics on Russian platinum production. In addition to the figures quoted of the platinum production at the Schouvaloff mine, the platinum mines of the successors of P. P. Demidoff, Pr. San Donato, for the first four months of the present year yielded 7 poods 9 pounds of precious metal, against 8 poods 3 pounds in the corresponding period of last year. According to the figures of the Russian Customs Department, the export of platinum in the months of January and February of this year declined to 22 poods from 46 poods in the corresponding period of 1906, but, on the other hand, it compares with only 10 poods in the corresponding months of 1905.

NITRATE OF SODA.

THE sailings for Europe from Chilian ports in the first half of July were 66,600 tons, and the total for the whole month is estimated at 112,000 tons, or practically the same as last year. Deliveries are said to have kept ahead of those in the corresponding period, which, of course, means that "invisible stocks" are being piled up, since the agricultural demand is completely at an end. All ports are congested, and Hamburg, the principal one, is apparently unable to take more nitrate for the present, as 7,000 tons have been ordered to Antwerp and Ostend, which on June 30 already had 19,000 tons in stock, compared with 7,675 tons a twelvemonth ago. Rotterdam, although equally over-supplied, has also had to receive another large cargo. United Kingdom ports are in the same position, and the quantity of nitrate of soda "financed" on onerous terms is altogether unusually large. The market is comatose, and while prices are nominally unaltered, considerable concessions would have to be made in order to tempt buyers either on the spot or forward. Quotations are again easier from Chili, at 8s. 10½d. per quintal, f.o.b., with no business passing.

BRITON FERRY CHEMICAL CO., LTD.—The directors have declared an interim dividend of 3d. per share, free of income tax, payable on August 1st to the shareholders on the books of the company on July 13th.

THE RETIREMENT OF PROF. LUNGE.—The *Neuen Zürcher Zeitung*, of the 12th inst., contains an account of the formal leave-taking of Professor Lunge, who has just resigned his professorship at the Zurich Polytechnicum. Professor Lunge's career and work in technological chemistry are too familiar to our readers to call for an elaborate eulogy in these columns. His standard works on "Sulphuric Acid and Alkali," "Coal-tar and Ammonia," and "The Distillation of Coal-Tar," together with his numerous contributions to periodical chemical literature, have amply established his reputation in the chemical industry throughout the world.

Reports of Companies.

ZINC CORPORATION.

The general manager's report for the half-year ending February 28th, states that Mr. A. L. Quencan, E.M., who was sent out by the directors to investigate the treatment of the company's material, reported, after exhausted investigation, that 1,300 tons treated in the experimental plant had yielded 348 tons of concentrates, with an average per ton of 44% zinc, 8% lead, and 8 ozs. of silver; further, Mr. Quencan reported a second test of 379 tons of tailings, treated for a recovery of 92 tons of concentrates, averaging per ton 43½% zinc, 10% lead, 9½ ozs. silver. With remodelled plant he would guarantee an extraction of 85% of the zinc. For the first treatment Mr. Quencan recommended the combined Potter process, magnetic separation for improvement of the zinc concentrates and separation of lead; he also recommended alterations to No. 2 plant.

Mr. Quencan's recommendations were carried out, and during the period—January 3rd to March 11th—under his direction, 493.3 tons of zinc concentrates were obtained, of a value of 40.1% zinc, 9.12% lead, and 9.75 ozs. of silver. The plant showed a capacity of about 150 tons a day. The value of the product, returning charges and without the magnetic purification concentrates, was about 8s. 6d. per ton of crude tailings; should the magnetic purification be successful the value would increase to 12s. 6d. a ton.

Experimental work, under the direction of Mr. Cole Huntley with the granulation process was started in March. The reconstructed plant, adopting the process to unit, started on April 6th; from then to May 4th, 3,970 tons of crudes were sent to the mill, from which 1,091 tons of concentrates were recovered. These were agreed with the smelters at an average value of 44.9% zinc, 9.6% lead, 10.1 ozs. of silver. The extraction averaged 73% of the zinc contents, the yield per ton of crude tailings being about 18s.6d. As soon as it was seen that a good yield could be obtained by this process, the reorganisation of the plant was put in hand, and pushed ahead as quickly as possible. Not only would the quality of the concentrates and extraction be improved by this new process, but the cost of working would be much less wear and tear, less consumption of chemicals, and a smaller degree of heat was necessary.

SPIES PETROLEUM CO., LTD.

The report of the directors for the year ending December 31 states that the net production of crude oil for the year, after deducting leakage and water, amounted to 6,057,077 poods. The stock on hand at January 1st, 1906, was 145,470 poods, which, with the net production during the year of 6,057,077 poods, and crude oil purchased, 7,000 poods, made a total of 6,209,547 poods. Of this 4,926,854 poods were sold and delivered, and 1,168,607 poods were used for fuel, leaving in stock on December 31st, 1906, 114,086 poods. The decrease of 780,691 poods in the net production as compared with the preceding year is entirely attributable to the effects of the strike, which lasted for 31 days, in the months of June and July. The crude oil sold and delivered as above realised 1,038,465.44 roubles, an average selling price of 21.077 copecks per pood. The net profit for the twelve months was £31,734., to which must be added the balance brought forward from last year, £6,347., making a total balance to the credit of profit and loss account as at January 1st of £38,081. Of this sum the directors have placed to general depreciation of leases, buildings, plant and machinery the sum of £19,000., and to reserve against fire and employers' liability insurance the sum of £2,000., leaving a balance of £17,081., out of which Russian taxes have to be provided. During the year the directors arranged for the acquisition of 90 dessiatines of oil-land in various parts of the Grozny oilfields, and since the close of the year the transfer of the titles to the company has been completed. Owing to the strike, drilling operations could not be commenced upon the new plots until the end of September. A satisfactory production has already been obtained from some of the wells drilled, and as the depth increases it is expected that the results will be still better. The total sum due as purchase-money for the lands bought during 1906, together with buildings and erections thereon, amounts to £63,255., of which £32,139. has been paid to date. The remainder of the purchase-money is due by instalments spread over one year and eight months. The sum of £21,781. was spent during the past year on the equipment and development of the new properties, and during the current year further considerable sums have been expended under the same head. The total amount expended to date on the acquisition, equipment and development of the properties purchased during 1906 exceeds £60,000. In view of the unsettled aspect of affairs at Grozny and of the commitments in connection with the new properties, the directors consider that it is in the best interests of the company that a dividend should not be declared at the moment, and propose to carry forward the balance. As mentioned in the circular to shareholders of January 24th, 60,000 shares, a portion of the unissued capital, have been allotted at par.

ASSAM OIL CO., LTD.

The report of the directors for the year ended December 31st states that the improvement in the main field mentioned in the last report has been continued, and that the directors consider the position in both maintenance and development to be satisfactory and to show good promise for the future. Some of the experimental wells have reached the oils, thus greatly improving the company's position. A great deal of work has been done at the refinery in 1906, enabling the products to be treated by better methods, and the whole process to be carried out in a more economical manner. The boiler stills have been found to be a little behind the other plant, and a small addition has been made, with the result that the capacity of the whole refinery has been appreciably increased. The board stated last year that they looked forward with confidence to the result of 1906. This confidence has, they think, been justified by the profit of £24,652. which the account shows. At the same time, though the profit is a good one, they do not, under present circumstances, feel justified in paying a dividend. They recommend that out of the above profits £17,500. be written off to depreciation account, leaving a balance of £7,152. to be added to the £6,710. brought forward from last year, and making the amount carried forward £13,862.

TYEE COPPER CO., LTD.

The directors' report for the year ending April 30th states that prospecting and developing at the mines have been carried on persistently during the past year, both at the Tyee and X.L. mines. The results, however, up to the present have not disclosed any new ore-bodies, although the general manager in his report, owing to his local knowledge, still maintains a hopeful attitude, and this seems justifiable in view of the large area of the company's property still unexplored. The board recommend a dividend for the year at the rate of 7½% per annum. This dividend will be payable on August 1st to all names standing on the register of members of the company on June 24th. It is a matter of congratulation, at this stage of the company's history, when the present known ore-bodies in the mine are being depleted, that the business in smelting customs ores has satisfactorily increased, and the directors look forward to considerable improvement in this department for the future. This may necessitate some additions to the plant.

NEW CENTENILLO SILVER-LEAD MINES CO., LTD.

The report for the year ended December 31st, 1906, states that the total production of ore was 9,883 tons, as compared with 9,653 tons in 1905. The total reserves were calculated at 9,000 tons on December 31st last, as compared with 9,500 tons on December 31st, 1905. The output for 1906 exceeded that for 1905 by 230 tons, while the reserves were increased by 100 tons. The profit amounted to £34,504., and the directors have transferred £5,000. of this to reserve, and written £8,630. off capital expenditure account. The whole of the fixed dividends on all classes of shares having been extinguished by the payment during 1906 of the 10% accumulated dividends on the ordinary shares outstanding on December 31st, 1905, and the fixed dividends for 1906 having also been paid, as stated above, it has become necessary to deal with the surplus profits available for distribution. The directors now recommend a dividend of 9.97% on the first preference shares, 9% on the second preference shares, and 9% on the ordinary shares. The total amount distributed in dividends out of the profits for 1906 will then be £23,563., of which the first preference shares will have had £3,295. or 21.97%, second preference shares £1,536., or 19%, ordinary shares £11,239., or 15%, as well as £7,492. accumulated dividends to December 31st, 1905, 10%, making 25%. The balance to be carried forward amounts to £5,783.

SIR OLIVER LODGE AND THE SMOKE PROBLEM.

AT the annual banquet of the Society of Chemical Industry, last week, Sir Oliver Lodge referred to the smoke problem. He described recent experiments in the direction of heating boilers without emission of smoke, and said he was very hopeful of a method recently devised, which proceeded on the right theoretical lines. The method was to be tried at the power station at Bournbrook, and at the same time the ordinary process was to be employed in another boiler with the same fuel and stoking. The main feature of the invention lay in taking the flame along an inner tube of fireclay, where the combustion could be completed, because the walls were red-hot, and these walls radiated heat to the boiler. The flame did not come in contact with the boiler. It was not extinguished, and the smoke was reduced to next to nothing. He emphasised that because he regarded the smokelessness of the air as a most vital matter in the condition of the life of the people, especially in the towns. As long as smoke was found to be necessary for the economical heating of water or metals and other substances, smoke was likely to continue, but if it were found that better results could be obtained by conditions which favoured complete combustion, and at the same time suppressed the smoke, then the atmosphere would begin to get clear. He had been preaching the theory of this for twenty years, and now he began to have hopes of seeing it put into practice.

Referring to Mr. Eustace Carey's presidential address to the members of the Society, Sir Oliver said Mr. Carey had been lamenting the departure of some of our chemical industries to other countries. He had also deplored the fact that institutions for the advancement of research were insufficiently endowed and supported. He (Sir Oliver) felt that, although they at the Birmingham University had received great support in the matter of buildings and equipment, they also wanted support for the students whom they turned out. It was no use a university turning out a number of well-equipped and well-trained students unless they were appreciated by the chemical manufacturers of the country—their future employers. In Germany they were told the manufacturers did realise the value of highly-trained men in industry and had created a demand for them. The Germans did not put men who were capable of real scientific inquiry and discovery to ordinary routine testing. The routine work had to be done, but he took it that organisation made it possible for it to be done by inferior and less trained persons. An appreciation of university training in this country by employers was, he thought, one of the things badly wanted. There were, however, many things about the educational system of this country of great interest, and one was that the technical schools were training men from below. They were training the workmen to become better foremen, to become, as it had been termed, the non-commissioned officers of industry. These men were of the utmost importance, and he thought he saw great signs that they were becoming eager for education. This was a warning to some of the cultured easy-going youths of the middle and upper classes that they would not have it their own way quite so much as they had, and that some of the lucrative appointments would be going to those really keen about education, and not to those just passing examinations because their parents had sent them to places of learning.

RUSSIAN GOLD-SMELTING LABORATORIES CLOSING DOWN.—It is stated that the Russo-Chinese Bank is closing its gold-smelting laboratories in Blagoveschtchensk and Nikolaieffsk on the Amur, because of the losses incurred in connection with these establishments.

THE RUSSIAN CHEMICAL MARKET.—The Odessa chemicals report for the latter half of June is to the effect that the demand was satisfactory, with prices maintained, although not with the previous firmness. English white lead is quoted 6 roubles 5.10 copecks, in three-pood casks; glycerine, 11r. to 11r. 25c.; sulphate of copper, 6r. 80-95c.; Caucasian potash, 2r. 35c.; Saratoff ditto, 2r. 65c.; Russian turpentine, 3r. 30c. to 3r. 40c.; Russian tannin, 38r. to 39r.; and foreign ditto 42r. to 43r. bichromate of potash, 9r. to 9r. 25c., all per pood. There is no special feature reported from *Novo Nikolaieffsk* as to the chemical market there. Sulphate of copper fetches 8r. 50c. to 9r. There is also little to report from St. Petersburg, where recent prices are quoted without special features.

IMPORTS OF METALS AND MINERALS.

THE following returns, which are taken from the foreign and colonial statistics of the United Kingdom, give the amount and value of metals and minerals imported during the month of June, 1907, as compared with June, 1906:—

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in Water-gas Producers. W. Clark, 53, Chancery Lane, London. (Communicated by the Dellwik-Fleischer Wasserges Ges. m. b. H., 14, New Mainzer Strasse, Frankfort A/Main, Germany.) British Patent, 18,256. August 14, 1906.

This invention relates to a water-gas producer, and has more particularly for its objects to avoid risk of explosion, to cheapen the cost of manufacture, and to render the working of the apparatus more simple than heretofore. The invention more especially relates to producers which work on the Dellwik system of water-gas generation, and which has hitherto been worked solely with compressed air. The producer is, however, worked with "suction air" (this being a feature which has been long known in connection with gas-producers), the plant being provided with a charging device in the form of a coal-feed hopper erected directly upon the producer and the gas main leading from the charging device to a fan. A by-pass pipe for the fan is provided for the purpose of heating up and of keeping the producer hot whilst at rest. The grate which has hitherto usually been employed for such producers is dispensed with, so that the producer charge rests immediately on the producer bottom or rather the resulting layer of ashes and slag. The steam pipe opens into the producer at the top, whilst the gas pipe is led off from the bottom of the producer, and not from below firebars, as heretofore, and discharges into the scrubber, which is arranged at a lower level. Here, solely, a known form of water-seal is provided, such that the issuing gas is able to easily pass into the scrubber, whilst the indrawing of the air when the producer is being blown up for heating, only results in the rise of the scrubber water into the gas pipe. By this means there is provided a general construction which possesses extreme simplicity, coupled with safety in operation.

An Improved Process of Distilling and Carbonising Certain Materials to Obtain Certain By-products Therefrom, and Apparatus for Carrying Out the Same. E. B. Robinson, "The Villa," Hurlet, near Glasgow, and W. C. Edwards, Rockland, Ontario, Canada. British Patent, 24,961. November 6, 1906.

This invention relates to improvements in the process for effecting the distillation or carbonisation or simultaneous distillation and carbonisation of substances such as sawdust, chipped wood, and wood refuse. ¶ The material is distilled and carbonised in a continuously rotating retort while continuously applying heat thereto, and the volatile and solid products are collected separately. The process is carried out in a cylindrical retort supported with its axis slightly inclined and rotated by any suitable means. The volatile products resulting from the operation of the process are withdrawn from the upper end of the retort and the non-volatile products from the lower end. The original specification should be consulted.

Metallurgical and Electrometallurgical Process for the Production of Pure Copper. L. Jumau, 18, Rue Mogodor, Paris. British Patent, 414, 1907. (Dated claimed under International Convention March 20, 1906.)

This invention relates to a process for obtaining pure copper from a solution of copper, which consists in treating a solution with sulphuric acid or a sulphite, separating the precipitate of cuprous sulphite thus obtained, treating part of the precipitate with an acid such as sulphuric acid which cannot form a cuprous salt, mixing the copper precipitated by this acid with the part of the cuprous sulphite which has not been treated with the acid, compressing this mixture into the form of plates on a suitable conducting support, and subjecting these plates as anodes to electrolysis in an electrolytic refining bath.

An Improved Detergent. H. Jackson, 10d, Powis Terrace, Bayswater, London. British Patent, 6,712. March 20, 1906.

The inventor claims:—(1.) A detergent consisting of water containing about 1% of ammonium oleate and free from a substantial excess of ammonia. (2.) A detergent consisting of a solution containing about 1% of ammonium oleate, made by adding oleic acid to water and then introducing ammonia in quantity only sufficient to dissolve the oleic acid. (3.) In washing with the detergent referred to in Claim (1), immersing the goods thereinto at the ordinary temperature.

WILLS.—Mr. Adam Crawford Bealey, J.P., of Manor House, Bury, head of the firm of A. C. Bealey and Son, chemical manufacturers, Radcliffe, who died April 15, left £249,885. The will provides that the executors may continue any charitable subscriptions and make grants to workpeople and servants in the employ of the firm.

ARTIFICIAL RUBIES.—A remarkable performance was given at the London Hippodrome, last week, by a young lady chemist from Vienna. The chemist, Miss Alice Norton, manufactures rubies and sapphires in full view of the audience. Miss Norton takes a quantity of ordinary London clay and places it in a crucible made of magnesium, adding, at the same time, given quantities of chromic acid. A powder, the composition of which is known only to Miss Norton, is thrown into the crucible, and the temperature of 5,000° F. employed first boils the mixture and then bakes it. Within five minutes a mass of quartz is formed that requires a heavy hammer to break. In this mass of quartz a large number of rubies of varying sizes are found. These are perfectly genuine. They will cut glass, and may be put to the severest test a jewel expert can devise.

Institute of Chemistry: July Examinations.—The following is the Pass List of the July examinations:—Of 28 candidates who entered for the Intermediate Examination, the following 22 passed: N. C. Akers, A. D. Black, J. Boyd, J. Brebner, M.A., B.Sc. (Aberdeen), R. Bruce, A. M. Cameron, B.Sc. (Edin.), H. R. Cooper, B.Sc. (Lond.), F. G. Crosse, W. C. Davis, M. C. Fletcher, H. L. Gammon, J. Gibbon, N. McN. Hyslop, R. D. Masson, R. L. Morris, J. W. H. Pattison, A. S. Petrie, O. D. Roberts, W. F. Russell, A. Sandeman, P. A. W. Self, B. Sc. (Lond.), and Miss M. M. J. Sutherland. In the Final Examination for the Associateship (A.I.C.), of 5 examined in the Branch of Mineral Chemistry, 3 passed: William Garsed, William Godden, Assoc.R.C.S. (Lond.), B.Sc. (Lond.), and Eric Hayward; of 2 examined in the Branch of Metallurgical Chemistry, 1 passed: E. B. Naylor, M.Sc. (Manchester); of 5 examined in Organic Chemistry, 3 passed: F. Baker, B.Sc. (Lond.), J. H. Lane, and B. D. W. Lutt; and of 7 (including 1 Associate) who entered in the Branch of the Analysis of Food and Drugs and of Water, including an examination in Therapeutics, Pharmacology and Microscopy, the following 4 passed: R. R. Bennett, F. M. Dyke, B.Sc. (Lond.), W. R. S. Ladell, and D. J. Law, B.Sc. (Lond.).

Legal Intelligence.

LIVERPOOL ASSIZES.

CIVIL COURT.

(Before Mr. Justice Lawrence and a Special Jury.)

LEVER BROS., LTD. *v.* THE ASSOCIATED NEWSPAPERS CO.

On Tuesday last, the trial was begun of the action for libel brought by Lever Brothers Ltd., against the Associated Newspapers Company, arising out of statements in the *Daily Mail* and London *Evening News* during the recent attempt to form a combination of soap manufacturers. The case, however, came to a sensational close on Wednesday. When the hearing was resumed, the leading counsel for the defendants announced that they had decided to entirely withdraw the defence. Every imputation which had been made upon Mr. Lever's honour would be unreservedly withdrawn and apologised for, and they were willing to pay substantial damages. After some conversation with counsel for the plaintiff, the damages were fixed at £50,000., and judgment was entered for that amount.

Mr. Justice Lawrence expressed his entire agreement with the course taken.

ZINC CORPORATION, LTD.—The chairman of this company has issued a circular announcing that the head office has been transferred to London, and that the London committee is now the board. The Hon. W. L. Baillieu and Mr. William Clark have resigned from the directorate, and Mr. Robert Skipwith, a partner in Messrs. Chaplin, Milne, Grenfell and Co., and Mr. Henry William Pelham Clinton, a director of the Ivanhoe Gold Corporation, Ltd., have been elected to fill the vacancies. Mr. Hoover, of Messrs. Bewick, Moreing and Co., will arrive in London from Melbourne about July 18th.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, June 24, 1907.

(Rate of Exchange, $4.87½ = £1.)

Nitrate of soda remains weak on spot, and may now be had at $2.50. per 100 lbs., futures from $2.45. up. Sulphate of ammonia varies from $3.05. to $3.10. per 100 lbs. Grey muriate for galvanizers is 6¼c., while white muriate, for electrical purposes, owing to the increased supply, ranges from 5⅞c. to 6¼c. Lump sal ammoniac, good white seconds, is 9¼c. per lb. Lump carbonate of ammonia is steady at 7⅞c. to 8c., and powdered is nominally 1% per lb. Sulphate of copper is now quoted at 7¼c. per lb. by the syndicate, and a little under by outside makers. White powdered arsenic is very dull on spot, at 7¼c. to 7½c. per lb., and futures are offered at 7⅛c. to 7⅜c. per lb. Red Saxony Arsenic is steady at 7½c. per lb. Bleaching powders are unchanged at $1.20 to $1.30 as to make. Alkali is 9½c. per lb., f.o.r. makers' works, for light 58% in bags. Caustic soda, 74%, is $2.05. per 100 lbs., same conditions. Calcined carbonate potash, 80-85% is 3⅜c. to 3⅝c. per lb., and hydrated 4⅛c. to 4⅜c.; contracts over next year are being packed at considerably less than this. Chlorates are unchanged under syndicate control. Bichromate of soda is 7¼c. to 7½c., and potash 8⅛c. to 9c. per lb., freight paid to principal points. Phosphate of soda is unchanged, at $1.85. per 100 lbs. Prussiate of soda is 9⅝c. to 10c., and weak; potash is 16c. per lb., and very dull. Oxalic acid remains scarce at 8⅞c. to 9c. for prompt delivery, and 8½c. to 8¾c. for futures.

TAR AND AMMONIA PRODUCTS.

FRIDAY.

Benzols weak, with values given at 8½d. for 90's, and 9d. for 50's. Crude tar, 16s. to 20s. per ton, Thames; 1½d. to 1⅝d. per gallon, delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, London, 26s. 6d., f.o.b., Gas Company, 30s. 6d.; East Coast, 25s. to 25s. 6d.; West Coast, 23s. 6d. to 24s. 6d.; next year, 2s. 6d. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 11½d.; pure, 1s. 8½d. to 1s. 9d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5⅝d.; 60%, 1s. 7½d.; 75%, 1s. 11¾d. to 2s.; crystals, 39-40, 5¾d.; 34-35, 5½d. Cresylic, 95%, 1s. 1½d. to 1s. 2d. Anthracene, 40 to 45 per cent. A, 1½d. to 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quiet. Nearest values are:—Beckton, £12. 2s. 6d.; Beckton terms, £11. 13s. 9d.; London, outside makes, £11. 17s. 6d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d. to £11. 18s. 9d.; Manchester, £11. 15s.; Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d.; Liverpool ordinary, 11s., and refined, 11s. 3d. Official quotations:—Cargoes, off coat or due, 10s. 11½d.; ditto, for prompt shipment, 11s. 3d.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: Standard brands, £93. to £93. 10s. cash, and £88. to £88. 5s., three months. Tin: G.M. quality, £183. to £183. 10s cash, and £180. to £180. 10s. three months; English, £186. Lead, soft foreign, July delivery, £20. 15s.; July shipment, £20. 10s.; September, £19. 10s.; English, £21. to £21. 5s. Spelter, ordinary brands, July, £24., ex ship; hard, £20. 5s., f.o.b. Antimony, £43. to £45.; ore, £10. to £10. 10s. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 16s. Nickel, £175. to £185. Pig-iron closing prices: Standard, 56s. 1½d. cash, and 56s. 3½d. one month; Cleveland, 56s. 6d. cash, and 56s. 8d. one month.

FERTILISER MATERIALS.

FRIDAY.

There is no new feature to report in the market for either phosphatic or ammoniacal material, there being very little business passing.

The recent values of both Florida and Tunisian phosphate rock are fully maintained, and further transactions for shipment, 1909 and 1910, are reported.

East Indian bone meal remains unchanged, at £5. 2s. 6d. per ton, nett cash, c.i.f. Liverpool, for shipment; and at £5. 7s. 6d. to £5. 12s. 6d. per ton, according to grist, ex store here, on spot.

Nitrate of soda remains quiet but steady, at 11s. per cwt., for ordinary 95% quality, and at 11s. 3d. per cwt. for refined, on spot.

MISCELLANEOUS CHEMICAL MARKET.

THURSDAY.

The market is somewhat quiet, and spot demand is not very active, but, on the whole, there is a fairly steady inquiry and values are well maintained. Caustic soda, unchanged, 70% £9. 15s.; 74% £10. 5s., f.o.b. Liverpool. A good deal of forward business has been done during the past week in bleaching powder, at prices under current rates; spot quotation, however, remains at £4. 10s., softwoods, free on rails. Chlorates are steady at 3½d. per lb. Bichromates unaltered in position or value. Rock sulphur, £4. 10s. on rails, in bulk. Saltcake, firm, at 40s. per ton, carriage paid. Sulphate of copper is in small request just now and price is easy at £31. per ton, f.o.b. Liverpool, for prompt shipment. White powdered arsenic is now coming forward more freely, and quotations are weaker at £32. 10s. Garston, for best brands. Carbonate and caustic potash continue in short supply, and prices are still on a high level. Prussiates quiet at 6d. and 3¾d. respectively for potash and soda. American acetate of lime steady at £8. 15s. ex ship; grey, £12. 10s. per ton. Acetate of of 'soda, £16. 15s., c.i.f. Foreign acetate of lead is a shade lower, white at £32., c.i.f.; brown, £26. 10s. per ton. Oxalic acid still scarce and dear at 4d. per lb.

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes steady at 35s. per cwt. Pearl ash quiet, with little offering. Bark also quiet. Berries dull, with no business reported. Logwood and fustic steady, with only a limited supply; cutch unchanged, with little business done. Beeswax: A parcel of Sierra Leone is reported sold at £6. 15s., and Chilian £7. 10s. per cwt. Gun copal: parcels have been sold at auction at 60s. to 71s. 6d. per cwt. Castor oil quiet, at 3¾d. for good seconds Calcutta, on spot, and 3¾d. per lb. for July-August shipments; first pressure French, 3¾d. to 3¾d.; second pressure 3¾d. Gambier: block steadily held at 18s. 6d. on spot, and 18s. for May-June, June-July, and July-August shipments; cubes, 28s. to 28s. 6d. on spot, and 27s. 6d. per cwt. for July-August. Shellac quiet: T.N. orange, on spot, 209s.; 205s. for August, and 195s. for October shipment. Glucose: American liquid, 43%, 10s. 6d. on spot; and 8s. for July shipment. American powdered starch, 10s. on spot, and 9s. 6d., c.i.f., for shipment; pearl, 9s. 4½d. on spot, and 9s., c.i.f., for shipment. Cream of tartar, 98% foreign powder, 81s.; 95%, 79s; Tartaric acid, English, on spot, 11¾d.; foreign, 11¼d. Citric acid: English, 1s. 11½d.; foreign, 1s. 11¼d.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

Palm oil in fair demand, sales including Grand Bassa and Dixcove on spot, £27. 10s.; Accra, on spot, £28. 10s.; July-August, £28. 12s. 6d.; Qua Eboe, July, £29. 12s. 6d.; Old Calabar, July, £29. 10s.; July-August, £29. 5s.; Emoe, July, £30. 5s., and July-August, £30.; Lagos, July, £30. 5s., and July-August £30. 5s.; Half Jack and Grand Bassam, July, £28. 5s. to £28. 10s.; Hard oils, near and July, £28. 10s., and July-August, £29. 10s., and August £29. 10s.; Benin, July, £29. 5s., and July-August £29. 10s. to £29. 12s. 6d.; Soft oils July, £29. 10s., and July-August, £29. 5s. to £30., and August £29. 10s. Olive oil firm, at 37s. to 38s. 10d. per tun, c.i.f. Linseed oil firm at 26s. 6d. to 27s. per cwt. for Liverpool makes in export casks. Cottonseed oil steady, at 31s. 6d. to 32s. per cwt., for Liverpool makes in export barrels. Rosin: 11s. 9d. for common; 11s. 10½d. for F; 12s. for G; 12s. 3d. for H; 12s. 6d. for I; 13s. 6d. for K; 14s. 3d. for M; 15s. 6d. for N; 16s. for WG; and 16s. 6d. for WW. Tallow steady at 30s. 6d. to 33s. 6d. for for North American; South American mutton, 34s. 4½d. to 34s. 6d. per cwt., c.i.f.; and South American beef 34s. 1½d. to 34s. 4½d., c.i.f. Petroleum firm at 6¾d. for Russian and Roumanian, and 6¾d. to 7⅞d. for American refined oils. Petroleum spirit steady, at 1s. 0¼d. to 1s. 3d. for American on spot. Turpentine steady at 43s. 3d. per cwt., on spot.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 10s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—The continued heavy arrivals of linseed have had a depressing effect upon the market for oils, and the prospects are still of larger supplies from South America and India. Refined cottonseed oil is affected the other way, a heavy shortage in the American crop and short supplies being likely to affect the market here, and to result in higher prices for future than present quotations. Amongst the principal imports here to date, as against the same period a year ago, are:—Wheat, 2,125,440 qrs., against 2,153,071 qrs.; flour, 104,535 cwts., against 109,983 cwts.; linseed, 307,738 qrs., against 285,322 qrs.; rapeseed, 47,288 qrs., against 41,025 qrs.; cottonseed, Egyptian, 119,891 tons; other kinds, 93,967 tons, against 103,702 tons and 74,054 tons respectively. Oilcake, 17,050 tons, against 24,761 tons; hemp, 77,080 cwts., against 101,005 cwts.; olive oil, 3,108 tuns, against 2,643 tuns; tar, 2,118 brls., against 1,912 brls. Amongst the weekly imports are lard, 4,366 cwts.; margarine, 870 cwts.; sugar, 23,132 cwts.; colours, 1,719 pkgs.; wool, 49,272 lbs.; hides, 485 cwts. Exports: Oil, 9,742 cwts.; colours, 2,016 pkgs.; chemicals, 2,961 pkgs.; cotton oil closes firm at 29s. naked, spot; July-August, 29s.; September-October, 27s. 9d.; November-April, 23s. 6d.; barrels, £1. 7s. 6d. and casks £1. per ton extra. Cottonseed, firm, but quiet, spot, £8. 5s.; July, £8. 3s. 9d., buyers; August, £8. 5s.; October, £7. 7s. 6d.; November-January £7. 5s., sellers. Exports of cottonseed oil for the week have been: Germany 100 tons, Holland 10, Norway 1, Sweden 4, total 115 tons. Linseed oil, quiet and lower, 24s. 7½d. naked spot; August, 24s.; September-December, 22s. 9d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports for the week: 3 tons Denmark, 6 Germany, 1 Holland, 4 Norway, total 14 tons. Linseed market slow, La Plata, 43s.; July-December 43s. 1½d.; August-September, 43s. 7½d.; new crop, December-January, 41s. 9d. Turpentine steady, spot, 42s. 6d.; July-December, 43s. 7½d.; September-December, 44s.; January-April, 45s.; Russian lower at 21s. 6d., business done. Rosin, firm, 11s. 3d. upwards, according to trade; olive oil firm £42.; castor oil unchanged; cod oil, £16. to £19.

CAKES.—Fresh business, quiet, with prices unchanged.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

Production of chemicals, owing to the Glasgow Fair holidays, is almost wholly stopped, and full resumption will not be reached for a week to come. Business transactions, however, are already beginning to assume some form, and though no great bulk is passing, the tone in the ordinary lines is fairly good, with prices on the whole well maintained. Sulphate of ammonia for spot business (no movement in forward) is about last week's position. Sulphate of copper is on a very uncertain market, owing to the fluctuations of the metal; the tendency to-day is to the fall. Mineral oils and paraffins are unchanged, and a good body of business is passing; whale oils on Glasgow market are on a range of 18s. to 25s., black to pale; Menhaden, 20s.; Newfoundland cod, £19.; pale seal, £25.

Chief prices current are:—Alum (in lump) £5. 5s. to £6. nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s. nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3½d. nett, f.o.b., Glasgow; bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b., Glasgow); bleaching powder, 35-37%, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16.; and boracic acid, £25., nett, Glasgow; caustic soda, white, 76%, £10. 10s.; 70-72%, £9. 15s.; 60-62%, £8. 15s.; and cream, 60-62%, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace) 2¼d., naked, f.a.s., Glasgow; nitrate of soda, 11s. 3d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 2¼d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6½d.; ordinary sorts, 6d. and 5¼d., open market prices for spot business at Glasgow and other big centres; ditto (lubricating) 805°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; and 860-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42., and £40. less 2½% any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s. nett Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d. prompt, f.o.b. Leith; sulphate of copper, £30. 17s. 6d. to £31., less 5% Liverpool, prompt.

TYNE CHEMICAL REPORT.

THURSDAY.

Market quiet with no material change in quotations. Soda crystals continue in steady demand locally at £3. 2s. 6d. per ton, gross weight. Caustic soda, 70%, £9. 15s., and 76-77%, £10. 10s. per ton. Bleaching powder, £5. to £5. 5s. per ton. Sulphur unchanged, at £5. to £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett, do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton; nett; hyposulphite of soda, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market rather quieter; the prices still continue firm; loading turns for gas and steam coals are rapidly filling up for two or three weeks ahead. Coke is also very steady, and the output is well taken up. To-day's quotations:—Best Northumbrian steam, 15s. to 15s. 6d. per ton; second qualities, 14s. 3d. to 14s. 6d. per ton; Northumbrian small coals, 10s. to 10s. 6d. per ton; best gas coals, 14s. 6d. to 15s. per ton; Durham bunker coals, 12s. 9d. to 13s. per ton; good coking coals, 13s. 6d. per ton; household coals, 15s. to 17s. per ton; foundry coke, 24s.

LATE ADVERTISEMENT.

ITALIAN Gentleman, 22, Diploma Turin University for Chemistry, desires post in Chemical, Colour and Varnish, or Dyeing Works, or Perfume and Soap Manufacturers. No salary required for a time; highest references.—Address, G. Della Beffa, 44, Finsbury Square, London, E.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."
"Expert, Manchester."

Our Telephone Numbers are:—

London: 13592, Central.
Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

THE NITRATE HALF-YEAR.

ACCORDING to official returns, the deliveries of nitrate of soda from European ports in the first six months of 1907 reached 940,790 tons, of which 73,730 tons in the United Kingdom and 867,060 tons on the Continent. Although only 23,310 tons larger than in the corresponding period last year, the total must be considered highly satisfactory, in view of the unfavourable circumstances under which it was attained, the season having been exceptionally backward, while the principal nitrate port, Hamburg, was in the throes of a strike at the busiest time; the ground lost there in March was not fully recovered, the half-year's deliveries being 380,000 tons, against 408,600 tons in 1906. France and Holland, however, came to the rescue, the deliveries from Dunkirk showing an increase of 20,000 tons, and those from Rotterdam (supplying Western Germany) being no less than 25,000 tons, or 50% larger. Belgium, on the other hand, fell short by about 10,000 tons, the previous season's experience being thus entirely reversed, as the last-named country and Hamburg then showed large increases and Dunkirk and Rotterdam large decreases, compared, with 1905. The Italian and other Southern ports have remained practically *in statu quo*.

Not a single extra acre was brought into cultivation in Europe, and the beet crop did not require more nitrate (its principal user, in fact, taking less), yet, as we have seen, the port deliveries exceeded the previous season's, selling prices being at the same time considerably higher. The inference is that much of the nitrate "delivered" remains unconsumed, and confirmation is supplied by the circumstance that Dunkirk and the Belgian ports are put down for 38,400 tons last month (out of the European total of 74,680 tons) against 25,680 tons in June, 1906. Imports were in both cases very heavy, but the season was of course at an end, the deliveries in Hamburg, for instance, being only 18,600 tons, compared with 25,300 tons in June last year. The difference between "deliveries" and "consumption," so often insisted on in these columns, has perhaps never received a better illustration. The United Kingdom still plays a minor part as a consumer of the Chilian fertiliser, the increase of 7,600 tons in the half-year's deliveries raising the total to only 73,730 tons, yet the British farmer manages to grow the largest crops in the world.

The United States have again failed to display the insatiable appetite for nitrate of soda generally attributed to them, the deliveries in the past six months having been only 160,000 tons, against 188,000 tons in 1906. Short supplies are supposed to be the cause of this anti-climax, and a remedy is being tardily provided in the shape of larger shipments in that direction. Taking shipments as deliveries in the case of other minor outlets (Japan, the Sandwich Islands, The Cape, etc.), we get 18,680 tons, against 21,567

Digitized by Google

tons last year. The world's total deliveries, January to June, 1907, therefore come out at 1,125,479 tons, compared with 1,127,047 tons in the corresponding six months last year, a somewhat inadequate result for the expenditure of about £40,000 on propaganda!

Production.—The output in Chili during the same period is officially given as 863,708 tons, against 830,021 tons in 1906 and 832,646 tons in 1905, the number of oficinas included in the returns having in the meantime increased from 107 to 126. Scarcity of labour and deficient water supply in the new Southern nitrate districts are the principal causes of this totally disproportionate expansion, but it must not be forgotten that whereas producers formerly used only fair-grade "caliche" or raw material, they now boil down a large proportion of "costra," or upper crust, yielding less nitrate. The extra quantity handled naturally involves an increase in the ratio of men employed to output obtained, yet it seems strange that only 152,718 tons of nitrate should have been produced last month, when 171,679 tons were manufactured in October under similar labour conditions. Again, only 677 tons more were produced in May last than in the same month in 1905, in spite of the addition of a score of producers with an unlimited supply of raw material. These are mysteries the secret of which is known only to those behind the scenes; the logical conclusion appears to be an eventual nitrate famine resulting from the numerous new works now in course of construction. It is nevertheless interesting to note that 19 oficinas, unbuilt two years ago, produced in May last 540,000 quintals out of the total Chilian output of 3,230,000 quintals. If men willingly risk their lives in the search for gold in inaccessible tropical and arctic regions, it will be strange indeed if they do not devise means to fully exploit equally valuable deposits within a stone's throw of the West Coast of South America.

Notwithstanding the scarcity of labour, ostensibly so deeply deplored, but in reality the safety-valve of the whole situation, all connected with the nitrate industry are enjoying a period of unparalleled prosperity. The producer, formerly well content with a profit of one shilling per quintal, is now making from two to three shillings, according to the quality of his grounds, or on an average over 100% on the prime cost of the manufactured article. A great deal is heard about the increase in cost of production through higher wages and dearer coal, but the advance is far outstripped by that in selling prices. The agents, who, besides selling the nitrate, supply all the requirements of the oficinas, are practically earning double commission, and importers now-a-days think nothing of a profit of 20s. per ton. Pluralist directors—in many cases agents—draw handsome fees, and the shareholders of moderately capitalised companies receive fancy dividends, the continuation of which in perpetuity seems somewhat prematurely to be taken for granted. In fact, the only non-participant in the nitrate millennium is the consumer who keeps the whole show going, yet does not count! His turn will come, however, as the present altogether artificial condition of the industry cannot be indefinitely prolonged.

The market can easily be rigged, but for some months to come nitrate of soda will be of little interest to the general consumer; there is, therefore, no occasion to enter into statistical details, beyond pointing out that the "visible supply" for Europe on June 30 was 291,460 tons, against 276,550 tons at the corresponding date in 1906, and that the "invisible" stocks are considerably larger than a twelvemonth ago. There is an increase of about 50,000 tons in stocks in Chili, and it is officially admitted that shipments will be heavier than last year; there are consequently, so far, no indications of a dearth of the Chilian fertiliser for next season.

MOTOR FUELS.

THE Fuels Committee of the Motor Union of Great Britain and Ireland, under the chairmanship of Dr. H. S. Hele-Shaw, F.R.S., which was appointed in September, 1906, "to inquire into the recent alarming rise in the price of petrol, and to report what steps, if any, can be taken to protect the interests of the private consumer," has now completed its labours. The work done by the committee is of considerable importance, and their report, which was presented to the members of the General Committee of the Union, at Southport, on Saturday last, contains many valuable facts and figures. The Union hope shortly to issue the report in its complete form, when it will include various appendices, among which will be found the evidence of the various witnesses examined, a bibliography of fuels for internal-combustion engines, and a brief description of the fuels mentioned in the report.

An important conclusion arrived at by the committee is that, owing to the demand for petrol increasing at a greater rate than its rate of increase of supply, a famine in this article may take place in the near future, and this view is supported by eminent authorities on the subject, whose opinions are quoted in the report. It is, of course, probable that new and unexpected sources of supply may be opened up, but geologists, who can speak on this subject with more assurance than in the case of most other mineral products, hold out very little hope of this.

As the demand for petrol continues to increase, it is well to consider, in view of the above-mentioned possible shortage, the introduction of efficient substitutes for petrol. The Committee have carefully considered the alternative fuels available, and have examined many witnesses on the subject, and they are of opinion that the one affording the greatest promise is alcohol, the supply of which is practically inexhaustible. The restrictions to its use, however, owing to the heavy duties imposed by the Excise authorities, and its present cost of manufacture, have prevented its general adoption as a fuel for power purposes in the United Kingdom. In other countries, such as France and Germany, the Government encourages the production of this spirit.

The great obstacle in the way of securing a reduction in the restrictive tax on alcohol is the view of the Excise authorities that such a step would be accompanied by the illicit use of alcohol for potable purposes; but it is pointed out that the use of an efficient denaturant would overcome this objection.

The report states that in use alcohol compares very favourably with petrol, and a comparison of the respective merits of these two fuels is given. Other possible substitutes for petrol which have been considered by the committee are heavier spirit, paraffin, naphtha, and benzol, but, in the opinion of the committee, the supply of these when exhausted, cannot be replaced by any known process, whereas alcohol, being derived from vegetation, may be produced in any desired quantity.

The following is a summary of the recommendations of the committee:—

(1.) That, being of opinion that the introduction of alcohol as a fuel in the future is by far the most promising substitute for petrol, they recommend:—

(*a*) That steps be taken to remove the restrictions on alcohol.

(*b*) That a prize be offered for the best essay on alcohol as a fuel.

(*c*) That trials be held to test the comparative merits of alcohol and petrol.

(2.) That the use of heavier spirit be encouraged.

(3.) That efforts be made to modify the present restrictions on the use and distribution of petrol.

(4.) That competitions for paraffin carburetters and vaporisers be organised.

(5.) That benzol, being a home production and more economical in use than petrol at the present time, be encouraged for use in motor-cars.

(6.) That a standing Fuels Committee of the Motor Union should be appointed for the purpose of giving effect to these recommendations.

CHEMICALS, ETC., IN SPAIN.

CADIZ.

MR. CONSUL A. KEYSER reports that the beet-sugar factory near Jerez has stopped work, the probable cause being arrangements with competitors in the sugar trade.

A trust has been recently formed in Paris under the name of "Cuivre et Pyrites," with a capital of 20,000,000 fr., in order to amalgamate the interests of the San Platon Mines with those of three other mining companies. Thus three important concerns will control practically the whole production of cupreous and iron pyrites in the Huelva province.

The sale and export of salt is the principal business in Cadiz. The production for 1906 may be put at 120,000 lastres. A lastre is 2,200 kilos. or about 2⅛ tons. The exports amount to about 85,000 lastres.

A "Concierto Salinero," an association established by all the salt merchants and exporters of this district, which had existed for twenty years, was broken up in February, 1906. Soon afterwards a new one was formed, called "Union de Fabricantes de Sales." A considerable number of salt growers and exporters remained out, with the result that keen competition ensued, causing prices to fall. For this reason the union lasted only six months and then dissolved. Since that date there has been no method for regulating the prices and keeping them high. The present prices are from 16 to 18 pesetas a lastre free alongside. But it is not anticipated that these will continue, since some growers, who have not established markets, are selling their salt at the "salinas," and will in future cease its production. Thus, with a shorter supply prices will certainly rise.

The pottery of San Juan, at Seville, merits attention as an instance of British commercial enterprise. In 1898 the pottery was acquired by its present owners, who rebuilt and fitted it up with machinery from the United Kingdom. The village of San Juan de Aznalfarache, situated on the right bank of the Guadalquivir, about three miles below Seville, is entirely supported by these works, where about 300 people are employed. The pottery finds a market in the peninsula, the Canary, and Balearic Islands. The work is supervised by British managers and the coals used come from Scotland. The ball clay, china clay, and china stone are imported from the South of England. The colours, cobalt and borax also come from the United Kingdom.

The new process for the extraction of oil is the patent of a French inventor named Tanquerel, who, having protected his rights in Spain, offered the patent to a group of capitalists interested in the production of oil in this district.

The process consists in extracting the oil by diffusion in a specially prepared water after the olives have been crushed. After witnessing experiments made in Algiers under the direction of the inventor, it was decided to try the process in an oil factory in Carmona, and a machine described as a diffuser was set up there, and a trial was made with the only olives then available, which happened to be of inferior quality. The season was far advanced, the fruit had been deteriorating since it had been gathered, and more time was lost preparing the apparatus. A brilliant oil of excellent quality was obtained, but the quantity fell far short of the expectation of the merchants, who, by this time, had offered to buy the patent if the trials were such as the inventor promised. He himself, after visiting the factory, declared that the low yield was due solely to the organic decomposition of the fruit experimented with; and it was therefore decided to postpone further experiments until the following season.

There are openings for nearly all British trades in the country, as there is always a market for cheap foreign goods appearing as something new. Novelties seldom come from the United Kingdom, and it is rarely that attempts are made to catch the public eye or to cater for foreign taste.

CORDOBA.

Mr. Vice-Consul Carr reports that the output of silver lead has been lower than previously, but the declared value was higher owing to the enhanced value of the peseta. Cerro Muriano is the only productive copper mine. A dressing plant and smelter are expected to be erected by the end of the year. An attempt is again being made to open up some antimony lodes near Copiel in view of the present high price of the metal. The owners are endeavouring to interest British capital in their mines. The wolfram mine at Montoro has increased its production from 64 tons in 1904 to 117 tons in 1906. The production of bismuth has risen from 4 tons in 1904 to 92 tons in 1906. The mines are owned by a British syndicate. The iron mines in Solobral have proved practically worthless, the quantity of available ore being very small.

The British smelter was short of ore last year owing to a falling-off in the production of the Linares mines. The French smelter at Peñarroya continues to forge ahead, the output for last year amounting to 48,000 tons of pig-lead and 2,347,260 ozs. fine silver. The ores smelted come from the provinces of Cordoba, Badajoz and Ciudad-Real.

Another bad year for olives has to be recorded, and the next crop has been jeopardised by severe frosts last winter and drought. The following has been the production during the last six years:—

Year.	Quantity. Gallons.
1906..	5,942,750
1905..	4,836,194
1904..	5,553,438
1903..	7,335,504
1902..	5,894,526
1901..	15,432,000

The production of ores in the province during 1905-06 was as follows:—

Class of Ore.	District.	1905. Quantity	1905. Declared Value.	1906. Quantity.	1906. Declared Value.
		Tons.	£	Tons.	£
Silver-lead	Santa Eufemia.	545	5,100	526	6,857
	Alcaracejos....	11,742	89,780	10,254	94,652
	Fuente Obejuna	4,577	30,160	4,173	34,512
	Villanueva de Cordoba....	20	32	..	..
	Montoro	90	213	125	440
	Posadas	1,010	8,955	983	9,469
Total.....	..	17,984	134,240	16,061	145,930
Zinc blende (argent)..	Posadas	6,471	9,928	7,142	11,756
Copper pyrites.....	Cordoba	301	1,320	860	6,285
Antimony	Espiel	..	..	10	53
Wolfram	Montoro	73	466	117	2,071
Bismuth	Conquista	26	400	92	1,655
Iron	Luque	33,650	3,580	9,720	1,195
Grand total....	..	58,505	149 931	34 002	168,945

Exchange, 28·40 pesetas = £1., average of year.

HUELVA.

Mr. Vice-Consul Bice reports that manganese ores also show a large increase, and in the earlier part of the year high prices ruled; in fact, it appeared that some consumers were compelled to pay almost any price in order to supply their requirements. The period under review has been an extremely important one for the mining industry of Huelva, owing to the high prices obtained for all ores, and great activity has ruled.

The Esperanza mines have been floated by a British company. The Campanario mine has been purchased by a French company, and the San Platon mine by a foreign firm. The prospectus of the Anglo-Spanish Mining Company, which aims at acquiring a group of copper mines in this district, has also been published recently. A Spanish company, Sociedad Anonima de Cobres de Nerva, with a capital of 20,000,000 pesetas, is now being formed to work a group of copper mines in the neighbourhood of Nerva. A trust has recently been formed in Paris with a capital of 20,000,000 fr. for the purpose of amalgamating the interests of the San Platon mine and three other mining companies.

PORTLAND CEMENT PRODUCTION IN JAPAN.—It is reported that the exports of Portland cement during 1906 showed a large increase, being 37,917 tons, as against 16,114 tons in 1905. This increase was principally due to the exceptional demand for cement from San Francisco after the earthquake and fire of April; but, although this demand may not be maintained in the future, the development of Manchuria and Corea will undoubtedly tend towards an increased export of cement from the Shimonoseki district. The two principal cement companies having works there are the Onoda and Asano. The former are situated at Onoda, 30 miles to the east of Shimonoseki, while the Asano works are at Moji. The annual producing capacity of each is 200,000 barrels.

HOUSE OF COMMONS.

FACTORIES AND WORKSHOPS INSPECTION.

On the 18th inst., in Committee of Supply, on the vote for the Home Office, the Home Secretary (Mr. H. Gladstone) in reviewing the work of his department, observed that it must be a matter of great satisfaction to the Committee that His Majesty had intimated his intention of establishing a medal for gallantry in saving life in mines. Passing to the report of the inspectors of factories and workshops, he said he regarded it as a report of great interest, a proof of the admirable work done by the official staff, but also of the heavy and perhaps the excessive labour of the present staff of inspectors. The one thing disturbing to his mind was the increased number of accidents. This matter necessarily attracted, and would continue to receive, serious attention. To what the increase was owing was to some extent a matter of speculation. Partly it was perhaps due to an increased use of mechanical power and increased number of factories, and partly to the improved method of reporting accidents. Among the general causes suggested was the less active supervision by employers consequent on their being covered by insurance. This was always one of the dangers which it was foreseen might accompany legislation on the lines of the Workmen's Compensation Act, and without attributing any special blame to employers, it was but human nature that there should be a relaxation of vigilance when there was no financial responsibility. On the other hand, on reading the report it was evident that some of the inspectors were impressed, he would not say with increasing, but continued carelessness on the part of the men. Constant familiarity with danger appeared to blunt the sense of danger; and that in itself created a trade danger which the Home Office understood, and as far as possible endeavoured to provide against. It was recognised that there must be continued and increased diligence on the part of the inspectorate.

Perhaps it would be well that he should mention a certain number of subjects discussed last year so as to show that the Government had been giving to them the promised attention. Among these was the question of poisoning by aniline, and by nitro and amido derivatives of benzene; a committee had been inquiring into that matter, and such poisoning had been added to the schedule of the Workmen's Compensation Act. The work of Commissions and committees had imposed very serious labour upon the department, and last year's legislation had materially interfered with their energies. The department was responsible for adding nine Acts to the Statute-Book, including the Workmen's Compensation Act, and other Acts of minor importance, which had entailed great labour. After summarising the work done on the industrial side of the department in issuing regulations, circulars, and orders, he said it was intended to start an inquiry into the conditions of labour in places where a high degree of humidity was combined with a high degree of heat. An inquiry which had taken place into an important accident in a match factory showed that the accident was due to causes which originated before the special regulations were brought into force. A return of accidents arising from poisoning was now available early in each year for the whole of the preceding year.

Last year, with the sanction of the Treasury, he increased the factory department staff by adding four inspectors, three lady inspectors, and four inspectors' assistants. He thought that was not bad for a start. The staff at present comprised 110 senior rank men; 13 lady inspectors; 5 inspectors or assistant inspectors for textile purposes; and 40 inspectors' assistants; making a total of 168. That was a large body, but when one remembered that there were 106,000 factories in the country, and considered other figures relating to their field of work, it was clear that a staff of 168 persons, however zealous, could not possibly cover the multifarious duties cast upon them under the Factory and Workshops Act. Not only was the field too wide for the labourers to deal with, but year by year the work was increasing in complexity and in difficulty. Year by year the need made itself felt of men of the highest possible intelligence, qualification and training. A further increase was necessary in justice to the staff and in justice to the industrial population. The chief inspector was preparing detailed statistics with regard to the five main divisions into which the country was divided, and the 47 districts into which it was subdivided, in order to arrive, as far as possible, at an accurate idea of what was essential at the present time. He had already a scheme under consideration for additional lady inspectors. The friendly consultations he had had with the Treasury encouraged the hope that there might be a substantial increase in the number of inspectors on the staff. He did not think the record of the year was a bad one, the work of the department showing an increase of 20%.

Sir C. Dilke, referring to phosphorus poisoning in the match trade, said we had proceeded in this country in recent years to hold ourselves up to other nations as being able to put an end by scientific apparatus to all industrial poisoning without forbidding the use of the dangerous ingredient itself. That applied both to phosphorus and to lead. He noted the fact that at the International Conference at Berne the statement was made by our Government that, as regards the prohibition of yellow phosphorus in matches, "France, Germany, Holland, Denmark, and Switzerland had already taken this step, and Italy had now decided to do so. In the United Kingdom reliance was placed upon special rules, and revision of these was now under consideration." The fact that we had had to revise the rules showed that we had not reached, in the phosphorus trades, a satisfactory position, and the case as regards lead was much stronger indeed. He went on to deal with the question of lead poisoning in the Potteries, deploring the increase in fatal cases among adults and the mortality among the infants of mothers engaged in trades in which lead was used. Some Government departments, he regretted to say, no longer insisted in their contracts that leadless glaze articles should be supplied.

Mr. Ramsay MacDonald asked that more power should be given to assistant inspectors under the Home Office, and that the wall dividing them from the higher grade of the inspectorate should be broken down. He also criticised adversely the character of the examination which the inspectors were required to pass, and he declared that the organisation of the Factory Department had forfeited the confidence of the trade unions of the country. There should be an inquiry into the matter and into the administration of the Factory and Workshops Act.

Mr. Herbert Samuel, who replied upon many of the points which had been raised, admitted the lamentable fact that the cases of lead poisoning increased last year; nevertheless they were fewer by 50% than the cases reported some years ago, and it was possible that then all the cases that occurred were not known. The Home Office was certainly not going to relax its efforts to stamp out industrial diseases, and a code of safety regulations was shortly to be issued for trades in which lead poisoning might be feared.

Mr. Gladstone, replying to a question which Mr. Akers-Douglas asked, stated that Messrs. Kynoch had given an assurance to the Home Office that they would discontinue the use of mercuric chloride in materials supplied for the department. He assured Sir C. Dilke that the officials would do everything they could to discourage the use of lead in the manufacture of pottery, and, touching upon the subject of life-saving appliances in mines, he expressed the opinion that as these appliances had not yet been perfected, the Government would not be justified in insisting upon their adoption. Answering Mr. Ramsay MacDonald, he refused absolutely to appoint a committee of inquiry into the administration of the Factory Department, for, in the first place, such inquiry was not necessary, and, in the second place, it would discourage the staff and impede the good work that was being done.

CHEMICALS IN JAVA.

In his report on the Trade and Commerce of Java for 1906, Mr. Consul Rose states that quinine was still far below the parity of bark. When bark prices stiffened the quinine also rose in value, but, unless the manufacturers sold the sulphate in advance, the year must have proved unprofitable to them.

The year's production of copra was small, and prices advanced steadily. Exports for the last four years have been:—1903, 15,155 tons; 1904, 21,391 tons; 1905, 95,173 tons; 1906, 45,406 tons.

The production of indigo shows a great decrease. In 1905 the figures were 769,993 lbs., in 1906 only 409,419 lbs. Most of it was sold locally, while the exports were principally to Japan. Out of 26 indigo estates, 13 have stopped producing. Tin also shows a falling-off. Shipments of Government tin were 9,807 tons as against 11,749 tons in 1904, while private tin was 1,935 tons as compared with 2,237 tons of the previous year.

Imports of fertilisers have remained much the same; practically all the imported sulphate of ammonia has been obtained from Europe. The petroleum import was 1,097,905 cases of American oil and 1,166,122 of Sumatra oil. The production of Java oil was 1,994,689 cases, as compared with 1,967,124 cases in 1905.

TURKISH TRADE IN 1906.

MONASTIR.

MR. CONSUL HEATHCOTE in his report on the trade of Monastir for 1906, states that, owing to a bad harvest, coupled with the unsettled state of the country, the quantities of exports have been considerably reduced. There has, however, been an increase in imports, as the numerous emigrants, who have left during the last few years, are remitting large sums of money to their families at home. This fact, coupled with the more regular payment of State employés, has set free large sums of money.

The import of Hungarian petroleum is increasing at the expense of Russian. Chemical products include acids in small quantities from Austria-Hungary, Belgium and France; matches from Austria-Hungary, Italy and Belgium; aniline and alizarine dyes from Germany; various dyes from Austria-Hungary, Belgium and Germany; starch from Austria-Hungary and France; drugs and medicines from Germany, France and Austria-Hungary (all quinine preparations from France); candles from Belgium and Turkey. Under this head German artificial indigo was first introduced in 1905, and drove out real indigo hitherto purchased from the United Kingdom.

The following shows the exports and imports during 1906:—

Exports.	Two Years' Average. £	1906. £	Country.	Per Cent.
Oil Seeds	156 ..	135	.. ..	—
Imports.				
Chemical Products	9,682 ..	9,200 ..	Belgium, France	—
			Germany, Italy,	—
			Aust.-Hungary	—
Oil	1,926 ..	3,680 ..	— ..	—
Petroleum	15,164 ..	13,248 ..	Hungary	40
			Russia	60
Salt	13,486 ..	13,800 ..	Turkey	—
Soap	17,480 ..	16,560 ..	„	—

BENGHAZY DISTRICT.

Mr. Consul Fontana reports that during the winter the sea overflows the waste tracts of land to the south-east of, and close to, the town, leaving deposits of salt which are extracted during summer. The salt, which is exported by the Administration of the Public Debt in sailing ships to Salonica and Beyrout, amounted to:—

Year.	Quantity. Kilos	Value. £
1905	8,000,000 ..	27,272
1906	6,000,000 ..	20,459

The principal imports during 1905-06 were:—

Country.		1905.	Value. £	1906.	Value. £
Canea, ...	Olive Oil, ...kilos,	540,000	1,600 ..	600,000,	20,600
Malta, Alexandria, ...	Petroleum ....cases,	10,000	3,000 ..	same as '05.	
Malta, France, Canea, Austria-Hungary, ...	Wine, Beer and Spirits, casks,	1,680	5,470 ..	1,260,	4 320
Malta, Tripoli, Italy, ..	Matches.....cases,	700	2,110 ..	600,	1,805
Misurata, Greece	Gunpowder, ..kilos,	8,000	10,400 ..	9 000	11,800

MANGANESE ORE IN RUSSIA.

THE Ministry of Trade and Industry has been approached by the Donets-Turiev and Russo-Belgian companies with a view to introducing an export duty on Russian manganese ore exported abroad, of 7¾d. a cwt. Such a duty would diminish the export of this ore, and would enable the metric works to increase their production of ferro-manganese for shipment to foreign markets. The price of manganese ore at Poti varied in 1906 from £1. 7s. 4d. to £1. 8s. 11d. a ton, whereas ferro-manganese fetched £10. a ton on exportation.

According to the Mining and Metallurgical Union of the South of Russia, the world's production of manganese averaged during the last three years about 870,969 tons a year. In 1903, 435,484 tons were exported from the Caucasus alone, exactly half the quantity required by the steel industries of all countries except Russia.

SALTPETRE IN RUSSIA—It is stated in a telegram from Tiflis that in the district of Ter, near the station of Nassran, deposits of saltpetre have been discovered.

THE FRANCO-BRITISH EXHIBITION, 1908.

THE Franco-British Exhibition of Science, Arts, and Industries was first proposed by the French Chamber of Commerce in London, towards the end of 1905, with the object of further increasing the commercial intercourse between the two countries. This proposal was received with so much approval on both sides of the Channel that the money necessary to ensure its successful organisation was readily subscribed. A site, comprising 140 acres, was taken at Shepherd's Bush, and the work of erecting the various buildings in connection with the Exhibition is now being rapidly pushed forward.

The Exhibition will be illustrative of every branch of science and industry, and as a similar exhibition has not been held in London since 1862, manufacturers will have the unique opportunity of showing in the British metropolis the progress made in every department of invention and industry since the middle of the last century. The arranging of each section will be relegated to a committee of experts on the various classes into which the exhibits are grouped. Manufacturers may therefore rely on their exhibits being displayed in the best possible manner, both from a commercial and artistic point of view.

The exhibits will be housed in twenty fire-proof buildings, the largest being the Engineering Hall, where every branch of the engineering trade will be represented. The Chemical Section is to be on an unprecedented scale, and will embrace applied chemistry, pharmacy, perfumery, the manufacture of paper, leather, tobacco, and matches, etc. General science, agriculture, different methods of transport, the liberal arts, and the textile trades, are a few of the other sections into which the Exhibition will be divided.

A special association has been formed to arrange for the representation of the French Colonies, and every endeavour is being made to ensure that the exhibits from the British Colonies shall be thoroughly representative of their class. Canada has already secured space to the extent of 120,000 square feet, and the manner in which the French Colonies are signifying their intention to exhibit shows a keen appreciation of the possibilities of the Exhibition.

Arrangements have been made by which the Central London Railway will extend their line to the grounds of the Exhibition, and the close proximity of existing railway stations will render it exceptionally easy of access. It is calculated that by the combined efforts of the various railway companies it will be possible to convey 800,000 persons to Shepherd's Bush in a single day. Other arrangements conducive to the convenience of visitors will be a system of commercial bureaux, where full information as to the locality and character of every exhibit can be obtained. By this means there will be a considerable saving of time and trouble in locating the display of any particular industry.

Although no Grand Prizes or medals will be granted, diplomas equivalent to such will be awarded exhibitors upon the report of an International Jury.

The Exhibition will be opened in May, 1908, and the allotment of space to French exhibits is being made by the Comité Français des Expositions à l'Etranger, 42, Rue du Louvre, Paris; and to those of British origin by the Franco-British Exhibition, 56, Victoria-street, London, S.W.

AUSTRALIAN CUSTOMS DECISIONS.

THE following are the principal decisions given in the recent decisions of the Australian Commonwealth with regard to the rates of duties levied on imported articles:—

Articles and how classed.	Rates of Import Duty.
Oil—Forminol—	
As oils in bulk, lubricating mineral ..	3d. per gallon.
Paints and colours—	
Golden sulphuret of antimony—	
As paints, dry colours, etc.	1s. per cwt., dry colour.
Malthoid roofing cement—	
As paints prepared for use	4s. per cwt.
Zinc oxide.—	
As paints, dry colours, etc.	1s. per cwt., dry colour.
Ukazone —	
As Insecticides, disinfectants, etc. ..	Free.

Reports of Companies.

TASMANIAN COPPER COMPANY, LTD.

The report for the year to December 31 states that a net profit of £33,028. is carried to profit allocation account, after the payment of debenture interest and the provision of reserves for British and Colonial taxes. Of this net profit, £8,339. was transferred to debenture redemption fund account, being the amount necessary to pay off all outstanding debentures, and the balance of £24,689. is carried to the balance sheet, reducing the debit balance on general expenses account to £12,884., which, it may be reasonably anticipated, will be cleared off in the current financial year. The development and the increased value of the company's properties, both in Tasmania and South Australia, justify a forward policy, rendering the raising of additional capital highly desirable.

"SHELL" TRANSPORT AND TRADING CO., LTD.

The report for the year to December 31 last states that, including the balance brought forward and after providing for depreciation, management and other expenses, the balance standing to the credit of the profit and loss account is £392,370., out of which the preference dividend (absorbing £50,000.) has been paid, leaving a balance of £342,370. at disposal. The directors recommend that £70,000. be appropriated from this as a provision to cover such expenditure as may be required to make the company's steamers and installations comply with the agreements with the Royal Dutch Company. The dividend already paid is the maximum permitted for 1906 under these agreements. By the arrangements with the Royal Dutch Company the agreement between this company and M. Samuel and Co. for the management of the company's affairs is cancelled as from January 1, and proposals for the future management will be placed before the shareholders. The directors announce the registration in Holland of the Bataafsche Petroleum Maatschappij and the registration in the United Kingdom of the Anglo Saxon Petroleum Company, Limited. These two companies are those established by the Royal Dutch Company and this company to carry out the agreements, which they feel assured will prove to the advantage of the company. During the year the volume of products shipped by the Nederlandsch Indische Industrie en Handel Maatschappij was satisfactory.

ANGLO-SWISS ASBESTOS COMPANY, LTD.

The report states that, owing to the fact that the company at the date of this balance-sheet had not arrived at a revenue-producing stage, no profit and loss account has been shown. The mine returns show 1,367 feet of driving in the solid rock to have been accomplished. The asbestos has varied in length up to 5½ inches, the quality having been maintained throughout. It was then decided to begin stoping in some of the drives, and, as a result, asbestos has just begun to arrive on this side, 26 tons having already been received in London, and the mine manager advising that a further 42 tons should be ready by the end of June. The price realised for substantially the whole of the asbestos already received is equal to that realised for the first quality Canadian. Considering the future prospects of the mine, there are important decisions yet to make, and difficulties inseparable from mining to overcome. One of the most pressing questions which has lately arisen, influencing seriously the working cost, is that of machinery both for drilling and for crushing. There are on the property two waterfalls. A report on the power obtainable from the same is to be made by the mine manager this summer, and the possibility of making use of the water-power available is receiving serious attention, particularly as, should such be decided upon, the raising of further working capital might be necessary.

Adulterated White Lead.—It is stated that a recent importation of white lead, adulterated with barium, was described on the kegs as "Ground White Lead, reduced." The term "reduced" does not, in this case, sufficiently denote "adulteration" for purposes of the Commerce Act, and it is laid down that in future the percentage of barium, or any other adulterant in white lead, must be as clearly and as permanently shown on the coverings of the goods as the ordinary trade description applied thereto, and delivery is not to be permitted until this condition is fulfilled.

JAPANESE TRADE IN 1906.

HAKODATE.

In his report on the trade of Hakodate for 1906, Mr. Vice-Consul Forster states that the trade of Hakodate has shared in the prosperity consequent on the termination of the Russo-Japanese war. During 1906 the imports were £231,490., as against £112,507. in 1905, and the exports for the same period £850,257., as against £525,580. The increase would have been greater if S. Saghalien had not passed into Japanese hands.

The total quantity of kerosene oil imported during 1906 was 4,521,579 gallons, valued at £84,432., as compared with 2,860,580 gallons, valued at £50,177., in 1905. The import from the United States remained the same as in 1905, the increase being due to heavy imports from Borneo.

The principal countries to which sulphur was exported were as follows:—

Country.	1906. Quantity. Tons	1906. Value. £	1905. Quantity. Tons.	1905. Value. £
United States ...	18,983	62,032	17,082	52,586
Canada	761	2,532	756	2,093
Australia, ...	8,286	27,310	4,710	16,039
Total	28,030	92,474	22,548	71,318

Manganese is produced in large quantities at the Birika mines, in Shiribeshi province, between Hakodate and Otaru. Hitherto the supply has been consumed locally, a small quantity only having been exported through Yokohama. The output was greatly increased last year, and direct exports were made to the following places:—

	1906. Quantity Lbs.	1906. Value. £	1905. Quantity. Lbs.	1905. Value. £
Liverpool	514,708	405	—	—
New York	3,082,017	2,045	415,452	375
Antwerp	6,037,800	3,100	—	—

NEW REGULATIONS UNDER THE WORKMEN'S COMPENSATION ACT.

The Home Secretary has issued the following regulations as to examinations of a workman by a medical practitioner provided and paid by the employer under the provisions of the first schedule to the Workmen's Compensation Act, 1906:—

(1) Where a workman has given notice of an accident or is in receipt of weekly payments under the Act he shall not be required to submit himself, against his will, for examination by a medical practitioner provided by the employer except at reasonable hours.

(2) A workman in receipt of weekly payments shall not be required, after a period of one month has elapsed from the date on which the first payment of compensation was made, or, if the first payment is made in obedience to the award of a committee or arbitrator, from the date of the award, to submit himself, against his will, for examination by a medical practitioner provided by the employer, except at the following intervals:—Once a week during the second and once a month during the third, fourth, fifth, and sixth months after the date of the first payment of the award, as the case may be, and thereafter once in every two months, provided that where after the second month an application has been made to the county (in Scotland the sheriff) court or to a committee for a review of the weekly payment, the workman may be required, pending and for the purposes of the settlement of the application, to submit himself to one additional examination.

Post Office Changes.—Several postal changes came into force on July 1. For the future the charge for the return of undelivered parcels will be discontinued, and such parcels will be returned free of charge. Wherever practicable in the international service, the maximum sum for which a single letter or parcel to a place abroad can be insured will be raised from £120. to £400., and the scale of fees will be reduced. Arrangements are being made for a direct and cheaper service to the Argentine Republic. The British postal service in Morocco has been extended.

Continental Notes.

IN the *Chemiker-Zeitung* for June 29, Emil Sauer continues his description of his process for the acidification of the wash with sulphuric acid in the manufacture of spirit, and points out in what respects he considers that his process is superior to others that have been brought forward. He claims that his method is much more easy to control than the lactic acid fermentation method, and that it satisfactorily fulfils its object in the working up of molasses as well as starchy materials.

In the same issue E. Wedekind writes on the production of zirconium carbide from zirconium ore. This is accomplished by heating the ore with finely divided carbon, but a very high temperature is necessary, and in the electric furnace about 1,000 amperes are required. When zirconium carbide is heated in a stream of nitrogen it does not give rise to a cyanide or a cyanamide derivative, but is converted into nitride; this, when fused with potash, evolves ammonia and leaves a residue, which burns when heated in the air.

Dr. P. Drawe describes a new laboratory drying apparatus for the rapid drying of small quantities of material for the purpose of analysis. It consists of a wide copper tube which passes horizontally through a bath of boiling water or other liquid. The material to be dried is introduced into this tube in a boat, and a current of coal-gas is passed over it, the gas being afterwards used to heat the apparatus.

In the issue of July 3, J. Fleischer and H. Frank give a simple and rapid method for estimating the amount of ether and alcohol in mixtures of the two liquids. The method consists in shaking the mixed liquid with petroleum spirit and water. The alcohol then separates in the lower layer with the water, and the ether in the upper layer with the hydrocarbon. By merely reading off the volumes of the two layers and deducting the volumes of water and petroleum spirit added, the volumes of ether and alcohol are at once obtained. Further, by taking the specific gravity of the aqueous alcohol, the amount of water in the alcohol used to make the ether-alcohol mixture can be calculated.

Prof. G. Kraemer writes at some length in the *Chemiker-Zeitung* for July 6 on the theory of the formation of mineral oil. He holds the opinion that petroleum deposits have been formed from vegetable and not animal matter, in much the same manner as moors are at the present time being formed. Oils resembling petroleum can be made by the dry distillation of both animal and vegetable matter, so that experiments upon these lines throw little light on the subject. The presence of nitrogen compounds is also no criterion, as they might as probably be derived from vegetable albuminoids as from animal ones. Of course there may have been some carcases of animals mixed with the vegetable deposits, but the amount of this constituent would be comparatively minute, as is the case in present-day moors and bogs. Kraemer, however, considers that the organic deposits from which the petroleum fields derive their origin were formed in the steep and narrow gulfs of glacial seas. The time required for the formation of these deposits and for their subsequent conversion into oil must have been immense.

In the issues of July 3, 6, and 10, there appears a series of contributions from Drs. F. Erban and A. Mebus, on the diazotisation of paranitraniline as sulphate.

The issue of the 6th also contains a paper by Dr. P. Heermann, on the specific gravity of tin chloride solutions. He has made a number of determinations between 10 and 15%, and between 20 and 30% Sn. The results agree well with those in Gerlach's table, but Heermann prefers to express the composition of the solutions in percentages of Sn instead of $SnCl_4 + 5H_2O$, as is done by Gerlach. The material used for the determinations was the technically pure salt made by Goldschmidt's process.

In the number for July 10, O. Kuhn discusses the question whether the laws of chemical combination are comprehensible without the atomic hypothesis, and he comes to the conclusion that they are not, and that the alternative theories that have been advanced by Wald and others are based on false mathematical reasoning.

H. Schlemmer describes two forms of glass still-head for laboratory use, but they are not constructed upon the scientific principles which characterise those that have been devised by Young.

In the issue of July 13 there is a description of the methods used in the Institute for Sugar-Industry in Berlin for the determination of the sugar in beet. The methods adopted are the alcoholic extraction methods, both with alcohol and water, by the processes of Pellet, Sachs-Le Docte and Primavesi.

There is also a description of an automatic montejus, and an account of the chemistry of milk during 1906.

The *Zentral-Blatt für die Kunstdünger Industrie* for May 21 contains articles on the following subjects:—The value of potash in agriculture and industry; northern bird guano; phosphate deposits in Arkansas; the farms of the Munich Refuse Utilisation Company; "Germanol"; some manuring experiments with the new nitrogenous fertilisers; and the use of compressed air in the analysis of superphosphates.

THE ROUMANIAN PETROLEUM INDUSTRY.

REPORTING on the trade of Roumania in 1906, Mr. Consul Wardrop observes that for the last five years petroleum has been the most important industry of Roumania, and it has made possible the general developement of industry, which seemed doubtful when the Industrial Law passed in 1887, by supplying fuel. The railways, the naval and mercantile fleet are worked by it, it checks the destruction of the forests, saves a large expenditure on foreign coal, guarantees fuel in case of war, lessens the dependence of the country on grain export alone for its prosperity, gives work to the people, taxes to the State, and traffic to the railways. The capital invested is chiefly German, and there is now no British company of any importance; about half the export hitherto has gone to France.

The total production of petroleum in 1906 was 887,091 tons, an increase of about 45% over 1905, when the production was 614,870 tons.

The following table shows the figures for the last fifty years:—

Year.	Quantity. Tons.	Value. Francs.
1857	257	11,000
1867	7,070	282,800
1877	15,100	604,000
1887	25,300	1,012,000
1897	110,000	4,400,000
1898	180,000	7,200,000
1899	250,000	10,000,000
1904	500,561	22,525,245
1905	614,870	27,669,155
1906	887,091	39,919,095
1857–1906	4,707,871	200,248,210

Note.—From 1857 to 1902 prices are calculated at 40 fr. per ton; from 1903 at 45 fr.

The only regions which produced more petroleum than Roumania in 1906 were:—

	Quantity. Metric tons.
United States	16,000,000
Russia	8,000,000
Dutch Indies	1,350,000

The following was the production of the refineries:—

	1905. Metric tons	1906. Metric tons.	Percentage of Increase.
Benzine ..	78,182	114,428	46
Lamp oil ..	153,499	221,683	44
Mineral oils ..	17,255	53,588	210
Residues ..	237,677	333,714	40

There is an increasing demand for residues for factories. The export in 1906 was 50% more than in 1905, and in 1905 33% more than in 1904.

	1904. Metric tons.	1905. Metric tons.	1906. Metric tons.
Crude gas oil, distilled, etc.	45,204	49,515	53,374
Refined (lamp oil) ..	78,270	118,134	196,631
Benzine	36,969	46,699	71,114
Total	160,443	214,348	321,119

Refined petrol thus shows an increase of 66.5% and benzine 52% over 1905. The benzine had mostly been sold for forward delivery, and did not, therefore, profit much by the high prices of 1906.

The United Kingdom was the chief purchaser of petroleum products, and took 28.4% of the whole export; but France and Germany took more benzine. It is interesting to note that the Argentine Republic and India were buyers, and that Germany, which has such a preponderant financial interest in the oilfields, bought only 15,565 tons of lamp oil. Constantza is the chief port of shipment (77%). Till 1898 crude alone was exported, but since then it has gone only to Austria-Hungary, while other

Digitized by Google

countries take: United Kingdom, residues and solar oil, for gas-making; France, distilled, for making lamp oil (distilled is put under the heading of lamp oil because it contains 85 to 90% of the latter, the remainder being only coloured matter, which enables it to enter duty free as crude), and benzine. Roumania has profited by the misfortunes of Baku, and the increase in the use of motors.

The importance of liquid fuel for marine engines and other purposes is becoming more fully realised. Roumania is very favourably situated geographically, and the new sources of supply which are constantly being discovered seem to give justification for the belief that she may gradually gain a dominant position in this article, in which she is already unrivalled from the point of view of quality. Experiments made by the Service Maritime Roumain have shown that on every trip made by their steamers there is a saving of more than £40, due to the use of this fuel, besides the additional advantages of cleanliness, saving of space and fewer hands. The Roumanian naval and mercantile fleet is the only one which exclusively uses petroleum fuel. At the oilfields themselves there is a large demand for residues, and it is reported that one of the works burned 12% of its production of crude for want of residues, caused by lack of satisfactory means of communication.

The small refineries have closed as larger ones have opened, but the existing 23 establishments have enormously increased their output during the last two years. 1906 was a prosperous year for them, and they have begun making the more expensive products, such as paraffin and various oils. They need large quantities of sulphuric acid, and a State protected factory for this article has been started at Câmpina.

The paid-up capital invested in the Roumanian oilfields is said to be :—

Nationality.	Amount. Francs.
German	74,000,000
French	31,000,000
Dutch	22,000,000
Roumanian	16,000,000
Italian	15,000,000
American	12,500,000
Belgian	5,000,000
British	3,000,000
Other nationalities	6,500,000
Total	185,000,000
	£
Equivalent in sterling ..	7,400,000

Some 15 new companies or amalgamations have been formed in 1906, and the new capital is about £2,400,000. The nationality of the new capital invested in 1906 was :—

Nationality.	Amount. Francs.
French	22,500,000
German	16,500,000
Italian	7,500,000
American	7,500,000
Dutch	2,500,000
Belgian	2,000,000
Roumanian	2,500,000
Total	61,000,000
	£
Equivalent in sterling ..	2,440,000

The German "Steaua Romana" has a capital of over £1,500,000., and French investors are interested in it to the extent of £250,000. It paid a dividend of 8% in 1904–05, and 6% in 1906.

Phosphate Works in Japan.—H.M. Consul at Shimonoseki reports that a very interesting feature of last year's import trade at that port was the arrival of the first shipment of phosphate rock from Christmas Island. During the year a company, the Osaka Ryuso Kabushiki Kwaisha (the Osaka Phosphate Company), was formed with the object of manufacturing superphosphates for fertilising purposes. Phosphate works were established at Fuku-ura on Hikoshima, an island at the western entrance to the Straits of Shimonoseki; and the first shipment of phosphate rock from Christmas Island arrived on August 26, per steamship "Zingara." The amount imported during the year was 5,459 tons in quantity and £18,255. in value.

WOLFRAM AND TUNGSTEN.

THE experiments of Mushet, the inventor of the self-hardening steel process, were bitter disappointments to him, owing to the disregard of the steel trade for his invention. Self-hardening steel was for years looked upon coldly by the trades of Sheffield and Germany; now the United Kingdom, Germany, and the United States of America are scrambling for supplies. Production in the United Kingdom is slowly being increased.

The West of England tin mines are now giving more attention to these ores, and there are one or two concerns operating chiefly for wolfram. Cumberland has a wolfram mine at Carrock, and the supplies are stated to be improving. Mushet's attention was directed to this property some twenty-six years ago, but no practical work resulted. The Carrock Mines, Ltd., was formed in 1904, with a nominal capital of £12,000., and after some two years or so it went into liquidation, the mine, plant, etc., being advertised for sale. Since then the concern has changed hands, and a new company is about to be formed. New South Wales, Victoria, and Tasmania are producing increased tonnages. Prices are at present firm, and tending upwards.

The deposition of the ore is generally in the older rocks and in vein form; the vein stone—usually quartz—has the ore disseminated in small irregular patches, but crushing and dressing operations are costly.

It is reported that rich ores of Scheelite have been located in the Borrowdale ranges of Cumberland. These formations are chiefly volcanic, and are traversed by numerous veins. The Borrowdale plumbago or black lead mine is also to be further opened up. Lead, blende, barytes, and plumbago, with small quantities of copper ore, also arsenical pyrites, tungsten and antimony, are being raised in the Alston Moor and Lake Districts of Cumberland.

THE ROYAL COMMISSION ON CANALS.

AT the last meeting of the Royal Commission on Canals and Waterways, Mr. L. John Groves, engineer to the Crinan Canal, supplemented evidence given on a former occasion. He said since he described the main features of a proposed enlarged and improved canal, he had been instructed by the Caledonian Canal Commissioners to make a special survey. The estimate for a fresh-water canal with two locks was £745,000., and this sum would include the necessary works for a water supply. For a sea water canal with a single large regulating lock the cost would be £790,000. He had heard it said that the proposed canal would unfairly compete with and injure the traffic of the west coast railways, but that would not be the case. In his opinion the increase from the tourist and yachting trade would largely augment their revenue. Electricity would be used for lighting the locks and also for motive power. The proposed depth of the canal was 21ft.

Answering Sir John Brunner, the witness said he was of opinion that a canal company should own the land on either bank of the waterway and that wharves should not become private property.

Mr. Charles Puller Hogg, M.Inst.C.E., of Glasgow, described the Crinan Canal, which is nine miles long, and was opened for traffic in 1801. Between the Clyde and the West Highlands the canal gave a sheltered passage 85 miles shorter than the exposed route round the Mull of Kintyre. The present canal was not altogether out of date, but it laboured under many disadvantages which restricted its usefulness and prevented its revenue expanding with the increasing trade of the country. It was recommended that a new canal should be cut from Lock Gilp, passing to the west of the town of Lochgilphead, and then following very closely the route of the existing canal for two or three miles, after which the route would diverge and pass through Crinan Moss and the estuary of the river Add, and terminate in Loch Crinan. The new canal would be wholly in cutting, and no embankments would be required. The present canal would have to be closed from three to four years while the new one was being constructed.

Gas Light and Coke Company.—The directors recommend a dividend at the rate of £4. 8s. per cent. per annum for the past half-year, carrying forward a balance of £306,992. A year ago the dividend was at the same rate, with £210,481. carried forward.

Digitized by Google

BEET-SUGAR PRODUCTION IN RUSSIA.

IN his annual report, Mr. Consul Smith (Kieff), states that the year 1906-07 produced, with 278 factories in operation, 1,286,456 tons of sugar, the largest quantity ever produced in Russia. The stock of sugar on hand was 100,386 tons, made up of 64,335 tons of the inviolable reserve, 10,079 of finished sugar, and 25,972 tons of products calculated upon the basis of white crystals. There will thus be an available supply of 1,386,842 tons, which is 257,810 tons in excess of the "nominal profitable production" stipulated for the year.

Of the afore mentioned 1,386,842 tons, 838,710 tons are for the home market and 112,903 for the inviolable reserve, the remainder being a "free reserve" available for export. The area under beet was 1,425,110 acres, giving a yield of roots of 142⅛ cwts. an acre, the yield, per acre, of 142.2 cwts. of roots, with an output of 13% of sugar, thus being 18.5 cwts. of sugar an acre.

In order to curtail the overproduction of sugar, Russia, in 1904, reduced the area under the cultivation of beetroot, but the restriction was of short duration, the area for 1905-06 showing an increase, over 1903, of 241,794 acres. The yield of roots has increased by 2,757,078 tons, and the production of sugar from 824,085 to 1,286,456 tons. The home consumption increases slowly, the last ten years' average being 40,323 tons, but 1906 shows an increase of only 21,984 tons. The average cash price upon the Kieff market for white crystals for the home market was £1. 7s. 9d. per cwt. during the first eight months, and £1. 6s. 1d. for the last four months. The fixed limit prices, £1. 8s. and £1. 7s. 1d. respectively, were exceeded on two occasions; at the end of October, when 32,258 tons were ordered to be taken from the "inviolable reserve" for the home market without paying the extra excise duty, and again at December 21st, when 64,516 tons from the "free reserve" were ordered to be put upon the home market, this increasing the quantity decreed by the Government for the home consumption by 96,774 tons, or to a total of 935,484 tons.

The actual quantity of sugar sold for home consumption in 1906 was 857,018 tons, made up of 567,286 tons of refined and 289,732 tons of white crystals, being 21,986 tons, or 2.6% more than in the previous year. The consumption for the last four years has been as follows:—

Year.	Quantity.	Increase.	Per cent.
	Tons.	Tons.	
1901-02	697,120	50,109	7.7
1902-03	721,787	24,667	3.5
1903-04	752,249	30,462	4.2
1904-05	835,032	82,783	11

The price of refined sugar upon the Kieff market showed a slightly downward tendency; for the first three months the price was £1. 15s. 10d. per cwt.; by the end of March there was a decline to £1. 15s. 3d. per cwt., and this price was maintained until the beginning of October, when there was a further drop to £1. 14s. per cwt., which held good until the first week of December, when £1. 13s. 3d. per cwt. was quoted, and this price held good until the end of the year.

The quantity of sugar exported from Russia in 1906, as given by the Association of Sugar Manufacturers, was 62,845 tons, a considerable decline when compared with the exports of former years. The following shows the different countries and the quantities exported to each during the last four years:—

	Quantity.			
	1906	1905	1904	1903
	Tons.	Tons.	Tons.	Tons.
Finland	5,352	18,461	34,421	97,823
Persia, Northern	50,579	50,890	51,685	63,575
Turkey	201	17,170	51,554	30,412
China	3,865	6,309	5,061	1,050
Afghanistan	200	248	315	530
Germany and Austria-Hungary (in transit) ..	2,627	4,120	26,905	43,044
Other countries	21	36	302	239
Total	62,845	97,234	170,243	236,673

The decrease in the export to Turkey—from 51,554 tons in 1904 to 201 tons in 1906—is ascribed by the Association of Sugar Manufacturers to the successful competition of the sugar of Western European countries, and principally from Austria-Hungary.

The markets of Western Europe are, through the Brussels Convention, closed to Russian-made sugar. The decline in the export trade, together with the increased production of the last campaign, shows that all is not well with the industry, and that, if a crisis is to be averted, steps must at once be taken to put it upon a sounder basis. Among the beet sugar producing countries Russia stands first as to the area of land under the cultivation of beet, second as regards the total area of roots, sugar, and number of factories, but lowest as regards yield of roots and sugar to the acre.

The trade of this district is most seriously affected by the shortage of railway rolling-stock, which is now unfortunately accepted as a chronic condition of affairs. During 1906 there was little or no improvement on the serious condition of 1905—by the beginning of 1906 the Russian railway system had to face 200,000 truck loads of goods lying at stations awaiting transport. This was aggravated by the preference which had to be given to the transport of grain to the famine districts, the return of troops from the Far East, and the carriage of fuel and raw materials to the various centres of industry. The sugar industry of this district alone requires sufficient rolling-stock to transport about:—Coal 516,129 tons, limestone 209,677 tons, beetroot 564,516 tons, raw sugar to refineries 435,484 tons, refined sugar for consumption 322,581 tons; total 2,048,387 tons.

In order to relieve this congestion, the Kieff Sugar Association in 1906 petitioned the Ministry of Ways and Communications to allow them to acquire their own rolling-stock, and to grant special rates to recoup them for the outlay of capital, etc. The Ministry could not agree to the proposal, and ordered 62 locomotives and 1,150 trucks to be sent to the relief of the South-Western Railway. By the middle of October the quantity of goods lying at the stations of the South-Western Railway equalled 24,000 truck-loads, and steps were then taken to ensure the grain, sugar, etc., being properly covered, and in December there were still 20,000 truck-loads awaiting transport.

Grave fears are entertained that the sugar industry is on the eve of a serious crisis. The immediate cause is said to be due to the fact that the Government, acting upon information communicated by interested speculators, ordered 64,516 tons from the free reserve to be put upon the home market last December in virtue of the conditions of the State control of the sugar trade. The result has been to bring down the market price from £1.6s. 2d., as fixed by the Ministry of Finance, to £1. 5s. 9d. and less per cwt. Serious consequences have followed this step. Buyers, who contract for sugar at the higher price, find it convenient to object to the poor quality or "the bad colour" of the sugar and refuse to accept delivery. The factories or sellers, now faced with a drop of 2s. to 2s. 3d. per cwt. and a glutted market, find it impossible to dispose of their products unless at a serious loss. This happening at the close of the manufacturing season, with large amounts payable for excise duty, the settlement with the planters for the roots supplied, as well as the approach of the annual settling for the goods supplied during the year, put many of the sugar factories to serious financial straits, and the general trade during the "contracts" or annual "fair" held during February (o.s.) was listless and depressed; money was scarce—a condition solely due to the stagnation in the sugar industry, which is the mainstay of the South-Western District of Russia.

THE SUGAR CONVENTION.—A white paper was issued on June 27th containing the text of the Foreign Secretary's despatch to the British Minister at Brussels on the 1st June respecting the International Sugar Convention, which was referred to by Sir Edward Grey in the House of Commons on June 8. In effect the despatch gives a year's notice to the contracting parties that the Government retire from the convention. It will be remembered that the Government came to the definite conclusion that the limitation of the sources from which sugar may enter the United Kingdom, whether by prohibition or by imposition of countervailing duties, is inconsistent with their declared policy and incompatible with the interests of British consumers and sugar-using manufacturers, and that consequently it will be impossible for them to continue to give effect to the provisions of the Convention requiring them to penalise sugars declared by the Permanent Commission to be bounty-fed.

Analytical Notes.

THE ESTIMATION OF INDIGOTIN IN COMMERCIAL INDIGO.

C. Bergdiel and R. V. Briggs (*Journ. Soc. Chem. Ind.*) show that the factor employed by Bloxam in his method (*Analyst*, 1907, 99) yielded too low results, and that these results should be multiplied by 1.026. If the sulphated solutions are not purified there is an error due to the sulphurous acid present in the sulphuric acid; this also reduces permanganate and is determined as indigotin. When the solutions are purified by salting out with potassium acetate, according to Bloxam's method, there is a loss of indigotin of 4% to 6%. The titrations with permanganate must be made at high dilutions (1 in 10,000), otherwise the results are too high. Bloxam's method, owing to its low temperature, is unsuitable for factory work in India.

THE ESTIMATION OF PARAFFIN IN OZOKERITE AND CERESIN.*

J. Mercusson and H. Schlüter (*Chem. Zeitung*) state that a large proportion of commercial "ceresins" are adulterated with paraffin. Ozokerite can be freed from tarry and other impurities by being heated to 180° C. with contentrated sulphuric acid, as in the manufacturing process, and the purified product is ceresin. For the detection of paraffin in ceresin, the method of Ulzer and Sommer (*Analyst*, 1906, 31, 119) has the drawback that the refraction of pure ceresins varies within wider limits than asserted. The authors have examined samples with refractions of 17.1 to 17.8, which would permit of the introduction of a large proportion of paraffin. The method is based upon the fact that 55 to 66% of ceresin hydrocarbons are precipitated from their solution in carbon bisulphide by the addition of a mixture of ether and alcohol, whereas paraffins of every description remain in solution. Three grammes of the sample, freed from rosin, saponifiable matters, etc., are heated with 30 cc. of carbon bisulphide beneath a reflux condenser. The solution is cooled to 25° C. (the more ceresin present the greater the turbidity), and mixed with 300c c. of a mixture of equal parts of 96% alcohol and ether at 25° C. The precipitate is rapidly separated, washed with 25 cc. of the alcohol-ether at 25° C., and dissolved off the filter with hot benzene, the solution evaporated in a tared vessel, and the residue weighed. Since 60% of precipitate (a) corresponds to 100% of ceresin the amount of paraffin (p) may be calculated by means of the formula:

$$p = 100 - \frac{100a}{60} = \frac{5}{3}(60 - a).$$

A ceresin is regarded as adulterated when the amount of precipitate is less than 50% of the sample, as pure when it exceeds 55%, and as suspicious when it is between 50 and 55%. In the last case the mother liquor should be concentrated by evaporation, and the fresh deposit, which separates on cooling, collected. This process is twice repeated, so that, in all, four fractions are obtained, each of which is tested for paraffin by the method of Ulzer and Sommer (*loc. cit.*). In the presence of paraffin the last precipitations are crystalline, the appearance being quite distinct from the crystalline reflection in the case of the last fractions of pure ceresins. The optical refraction shows a marked decrease between the first and second fractions from mixtures of ceresin and paraffin, whereas with pure ceresins there is a gradual fall. Thus, a pure ceresin with refraction of 13.8 at 90° C. yielded a first fraction with a reading of 14.6 and a second with 11.0. The corresponding readings with a ceresin containing paraffin were 7.5, 16.7, and 6.9. An advantage of the method is that the amount of the first precipitate is approximately constant, even in the case of pure ceresins which differ widely from one another in melting-point and refractive power.

THE ESTIMATION OF WOOD SPIRIT IN ACETONE.*

F. W. Babington (*Journ. Soc. Chem. Ind.*) describes a method for discovering the amount of methyl alcohol in acetone. In this method the sample is distilled with boric acid, the quantity of boric ester distilling over being a measure of the methyl alcohol. The operation is as follows: Twenty-five cc. of the sample and two grammes of boric acid are placed in a fractional distillation flask provided with a tapped funnel, and connected with a condenser and trapped receiver. Twenty cc. of glycerol and 20 cc. of water are placed in the receiver, and the contents of the flask are distilled to dryness. When cool, 25 cc. of water are added through the tapped funnel, the distillation of this serving the purpose of washing the condenser. The glycerol solution of the boric ester is then titrated with $\frac{N}{2}$ sodium hydroxide solution, using phenolphthalein as indicator.

* *Analyst* abstract.

THE ESTIMATION OF FOREIGN MINERAL MATTER IN FEEDING STUFFS BY MEANS OF CARBON TETRACHLORIDE.*

J. Gram (*Chem. Zeit.*) recommends, for the sedimentation method, carbon tetrachloride in place of chloroform containing bromoform. Whichever liquid be used, however, the method is open to the objection that, in hard-pressed oil-cake, the whole of the sand is not separated in this way. Trituration with carbon tetrachloride will yield an additional 0.1 to 0.4%, but even then the results do not agree with those in which the ash is extracted with acid and alkali. The latter method, again, has the drawback that the silica in the husks of many seeds is only partially dissolved by the hot alkali solution, and the residue is thus determined as sand; whilst, on the other hand, any foreign calcium carbonate is dissolved by the acid and escapes estimation. From comparative analyses the author concludes that for strongly compressed meals the ash-extraction method is preferable, whilst for feeding stuffs containing husks rich in silica the sedimentation is more accurate. In the case of unpressed feeding-stuffs poor in silica, such as rye bran, the results obtained by either method are concordant.

* *Analyst* abstract.

TRADE OF HAYTI IN 1906.

REPORTING on the trade of Hayti for the year 1906, Mr. Consul-General Vansittart states that only 4,837,560 lbs. of guaiacum were exported as against 9 million odd in 1905, and 4,982,502 lbs. in 1904.

Import duties on soap, which were made payable in American gold by law of August 21, 1906, were changed by a decree of the President of the Republic, to take effect on November 1, 1906, to the duties existing previous to the law of August 21, viz., duties on soap to be paid in gourdes, national currency. This means that soap now pays 2s. instead of 8s. 11½d. per 100 lbs. The common soap is almost entirely imported from the United States, but there are three soap factories established in this Republic, one at Port-au-Prince and the others at Cape Hayti and Aux Cayes. Higher grade soaps, for toilet purposes, are imported from France. Very little comes from the United Kingdom.

There is a candle factory, as well as a match factory, in Port-au-Prince; but both candles and matches are largely imported from Germany.

During the last session of the Chambers, the following concessions were given to Haytian citizens:—(1) A concession to refine petroleum and to construct on the coast, or in the interior of the country, reservoirs to contain raw petroleum and its products. (2) A concession for the establishment of a manufactory to obtain the extract, or colouring substance, from campeche (logwood).

EXPLOSIVES FACTORIES AND MAGAZINES.—The annual report of His Majesty's Inspectors of Explosives, for the year 1906, states that no reason has been found to complain of any falling-off in the general condition of factories and magazines, and there has been no occasion for legal proceedings for any irregularity brought to light by inspectors to be instituted. Notwithstanding the large increase in the manufacture of explosives, the average number of deaths has greatly decreased since the passing of the Explosives Act, whereas the number of fatal accidents with explosives under conditions to which the Act does not apply appears to increase with the extension of trade. The number of magazines under continuing certificates and licence was 432, the same as the previous year. During the year 466 visits were made to magazines, and in very few instances serious defects or irregularities were found, the general condition of magazines throughout the kingdom being highly satisfactory. There were seizures at four magazines containing an unauthorised ingredient manufactured by Messrs. Kynoch Limited.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

An Electric Plant for Producing Chemical Reactions. I. Moscicki, Freiburg, Switzerland. British Patent, 14,259. (Date claimed under International Convention, January 17, 1906.)

The inventor observes that in the employment of alternating-current arc flames for chemical reactions, auxiliary means are employed with advantage, in order that with the low tension it may be possible to have a suitably greater distance than the normal between the electrodes. This invention relates to the technical carrying out of an arrangement by means of which it is possible, with relatively very low tension, to bridge over very considerable distances between the electrodes with the electric flame. It is, of course, not new to start an arc between two electrodes by applying a high-tension current so as to cause a spark to jump across the gap, and thereafter to maintain the arc with low-tension current. Also, in an arrangement of circuits heretofore proposed, two separate electrodes were inserted in a generating circuit, and were connected through coils and spark gaps with the secondary winding of an induction coil fitted with the usual condenser, but this circuit had for its object the production of successive and quick interruptions in the generating circuit.

The present invention is distinguished by the application to the electrodes in a generator circuit of the ends of the secondary winding of a transformer, which winding is also connected with another spark gap in parallel with the gap between the electrodes. The invention is further distinguished by condensers arranged in series with each spark gap, and by the arrangement between the electrodes and the generator circuit of devices for preventing oscillating discharges from reaching the generator circuit. The original specification, with the drawings, should be consulted.

Apparatus for the Electrolytic Production and Separate Collection of Gases. Jasper Wetter, 37 and 39, Essex Street, Strand, London. (Communicated by Elektrizitäts Akt.-Ges., vormals Schuckert and Co., Nürnberg, Bavaria.) British Patent, 17,981. August 10, 1906

The inventor claims:—In apparatus for the electrolytic production and separate collection of gases having an electrode formed by the walls of the electrolyte-receptacle and separated from the other electrode only by an insulated bell or hood mounted over the same, the combination of a receptacle-electrode having an upper part adapted to serve for collecting gas and to dip into the electrolyte, with an inner electrode arranged within a bell or hood and extending below the same to such a depth that electric current will not pass from the same to the upper part of the receptacle-electrode, and that consequently the generation of gas on the said part is prevented.

Improvements in Stirring Arms for Roasting Furnaces. C. Lean, Thanet House, Temple Bar, London. (Communicated by Maschinenbau Anstalt Humboldt, Kalk, near Cologne, Germany.) British Patent, 27,061. November 28, 1906

The inventor observes that in the case of the well-known multiple-storey roasting furnaces, raking-arms are employed for thoroughly stirring and moving forward the material being roasted, which arms are usually arranged on the right and left of the central column, that is, diametrically opposite one another, and are connected firmly with the stirring-shaft and yet detachably. Means enabling this arrangement to be employed have been proposed in the Specifications of Newton (6,931, 1905) and of Herreshoff (27,393, 1898). The necessity of having readily interchangeable stirring-arms is due to the arms breaking comparatively frequently, which is caused by the radial and tangential thrusts acting on the raking-arms, and it is very difficult to combine interchangeability with firm, secure attachment.

The proposal to form the two stirring-arms of a furnace-chamber as a single member passing across a diameter of the furnace interior and passing diametrically through the shaft has, in spite of some advantages, the serious disadvantage that the operation of interchanging stirring-arms which are twice as long and heavy as ordinary ones presents considerable difficulty. The object of the present invention is to remove this defect, and to provide means for attaching stirring-arms which, while giving the requisite security, permit them to be readily interchanged. The essence of the invention consists in forming each stirring-arm as a two-armed lever, and in so supporting it in or on the shaft that it can be disengaged when the shaft is stationary by giving it a slight movement in a plane substantially at right angles to the shaft in the direction in which the shaft normally rotates. The turning moment exerted on the stirring-arm in consequence of the resistance offered by the material being roasted is consequently taken up by the shaft, or when two stirring-arms are arranged in one furnace-chamber the turning-moments of two diametrically opposite stirring-arms neutralise each other.

Improvements in Electric Transformer Furnaces. O. Frick, Saltsjöbaden, Sweden. British Patent, 29,371. (Date claimed under International Convention, December 27, 1905.)

This invention is to effect, by means of an improved arrangement of the primary winding, an essential reduction of the primary leaking field and of the self-induction in the primary circuit caused by the leaking field, in order to obtain a more favourable value of the power factor of the supply circuit. The invention refers only to that type of transformer furnaces in which the iron core is arranged in such a way that its outer parts are so remote from the greater part of the primary coils and the bath, that they do not, or only to a small extent, enter the magnetic leaking fields. The primary leaking field surrounds the primary coil on all sides for a distance about equal to the distance between the coil and the middle of the secondary.

The invention consists in arranging the primary winding so as to enclose more than one side of the hearth. The primary winding may be divided in coils, which are separated from each other and placed at opposite sides of the hearth, or they may enclose the latter at two or more adjacent sides.

RUSSIAN PHOSPHORITE DEPOSITS.—The *Viestnik Finanssoff* publishes an article on the question of Russian phosphorite deposits. Anxiety has been expressed in Russia lest this valuable fertiliser should be sold in too great quantities to foreigners. The writer points out that the reserves in Podobia and Bessarabia are practically inexhaustible. The areas prospected for phosphorite have been found to contain the article in such quantities and in so many places that the writer of the article holds that there is no need whatever to impose a prohibitive export duty on the export. Hitherto the output has been limited because the home agriculturist did not appreciate its value, and the difficulties in the way of the export were too great, while even the removal of the export duty previously imposed did but little to assist that particular method of disposing of it. Considerable quantities are now used in the iron works. The writer cites a large number of districts, besides those named, where the article is found in abundance. There are several factories in Russia treating this mineral, the principal of which are the "Lovitch" and "Strzhemeschitsk," which are both essentially superphosphate factories, and the former handles as much as 300,000 poods annually. The production from 1899 to 1902 inclusive has been 884,473 poods, 1,434,704 poods, 840,000 poods, and 693,000 poods, whilst that for 1903 and 1904 respectively was 640,000 poods and 1,215,000 poods.

Trade Notes.

THE BRITISH PHARMACEUTICAL CONFERENCE met in Manchester on Tuesday last, Mr. Thomas Tyrer presiding. The president's address dealt with matters of pharmaceutical interest and emphasised the importance of research. A number of papers were afterwards read, and a varied social programme was provided. It was decided to meet in Aberdeen next year.

GERMAN COPPER CONSUMPTION.—The *Information* publishes a message from Hamburg stating that, at a meeting of the Copper Industry Union of Germany, Herr Rhumkorff said, on the strength of information he had from the Ministry of the Colonies, Germany will soon be able to get all the copper required for her consumption from her own trans-oceanic possessions, without having recourse to the foreigner.—The statement has led the journal to analyse the German copper supplies situation, and it finds that Germany occupies the first position in Europe as a consumer of copper, and that she used 150,000 tons in the year 1906, whilst her production, limited almost entirely to the Mansfeld centre, amounted to about 42,000 tons. The United States sold her 108,000 tons last year, or a quarter of its total production, and yet she had to get 18,000 tons from other countries, such as England, Spain, Japan, etc. Obviously, Germany is expecting to get her copper from Damaraland, the acquisition of which, and the approaches thereto, nearly got her into trouble with the English in the past. Nevertheless, this reserve was left alone for many years on account of the difficulty as to ways of communication, for the price of copper then—*i.e.*, £40. to £50. per ton—was not sufficient to pay the expenses of making them. Now, however, the 600 kilometres of railway connecting the Otavi mines with the coast have been completed, and great efforts are being exerted to make a fine harbour of Swakopmund on the Atlantic, where the line terminates. But, surely, the production of Damaraland is over-estimated. To expect over a hundred thousand tons there is to ask as much as is got from Michigan, Arizona or Montana; whilst, according to the calculation of the Otavi Minen Gesellschaft, which is the only company seriously dealing with the Otavi deposits, it expects to get 7,000 tons of metallic copper yearly. The journal concludes:—The day appears to be far off when the copper-laden vessels from Swakopmund or Luderitz Bay will cause any anxiety to the producing centres of America.—*Financier and Bullionist.*

PATENT LAW AMENDMENT.—In opening a recent discussion on the patent laws, Sir Joseph Lawrence said that in the year 1818 a serious robbery took place in Plymouth Dockyard. His (the speaker's) grandfather was at that time in business in the port in supplying hardware and other goods to the Fleet. The Government offered a reward of £100. for a lock which could not be picked. His grandfather secured the reward, and thereafter devoted himself to the manufacture of locks and safes. That was an illustration of the very common case of a business beginning with and depending upon a patent. At the present time a very important and far-reaching Bill was being considered and was now in the Committee stage, and he gave the greatest credit to the President of the Board of Trade for what he was doing in regard to the reform of patent law. Sir Joseph Lawrence said that they did not ask for anything unreasonable, but simply for what had been a condition precedent to the grant of a patent monopoly ages ago, that a patentee should bring a new industry into the country and give employment to the people. They ask the Government to insist that if a foreigner took out a patent in this country he should come here and work it. Mr. Evans-Jackson said many of the patents were absolutely worthless. The only proper course, in his opinion, was to grant a patent to the man who applied for it, and on the terms he applied for it—namely, that he was the first and the true inventor.—Mr. Astbury, K.C., M.P., said that he believed the object of the President of the Board of Trade in the Bill now before Parliament was to encourage real invention; that when the invention was patented in this country it should be worked here for the benefit of this country; and that, if it was an invention necessary to many branches of an industry, the mere working of it by an owner of the patent should not be sufficient if those other branches of industry were handicapped by being unable to work it. In that case they should be entitled to have a compulsory licence from the patentee at a reasonable cost even during the first 14 years.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, July 10, 1907.

(Rate of Exchange, $4.87½ = £1.)

Nitrate of soda remains somewhat dull, at $2.55. per 100 lbs. for spot, and $2.47½. for shipments. Sulphate of ammonia is unchanged at $3.07½ per 100 lbs. Grey muriate is going into the usual consuming channels at 6c. to 6¼c. per lb.; and white electrical muriate is somewhat cheaper, owing to the accumulated stocks, at 5¾c. to 6c. per lb. Lump sal ammoniac is 9¼c. for good white seconds. Lump carbonate of ammonia is steady at 7¾c. to 8c. per lb. Sulphate copper is held by the Syndicate at 7¼c. per lb., with some outside to be had at a shade under. White powdered arsenic remains very dull, and is fractionally lower, at 7¼c. to 7¼c. per lb. Red Saxony arsenic is steady, at 7¼c. per lb. Bleaching powders are slow of sale at $1.25. to $1.35. per 100 lbs., as to make. Alkali, 58%, in bags, is quoted at 9½c. per lb., f.o.r. makers' works. Caustic soda, 74%, is $2.05. per 100 lbs., same conditions. Carbonate of potash, 80-85%, 3¾c. to 3¾c. per lb., and hydrated, same test, 4¾c. to 4¾c. per lb. Chlorate of soda is 8½c. and potash 8¾c. for crystals, f.o.r. makers' works. Bichromates remain firm at the recent advance, and are generally quoted at 7¾c. for the first, and 8¾c. for the last. Prussiates are dull, soda being 9¼c. to 9¾c.; and potash, 15¾c. to 16c. Oxalic acid remains scarce, and in good demand at 8¼c. to 9c. per lb. for prompt, while antimony products all continue downwards.

TAR AND AMMONIA PRODUCTS.

FRIDAY.

Benzols quiet, with values given at 8¼d. to 8½d. for 90's, and 9d. for 50-90's. Crude tar, 16s. to 20s. per ton Thames, 1⅛d. to 1⅜d. per gallon, delivered; refined tar, 12s. per barrel, Gas Company, 12s. 6d.; pitch, London, 26s. to 26s. 6d., f.o.b., Gas Company 30s. 6d., East Coast 25s. to 25s. 6d., West Coast 24s. to 24s. 6d.; next year 2s. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol 11½d., pure 1s. 8½d. to 1s. 9d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5⅝d.; 60%, 1s. 8d.; 75%, 1s. 11⅜d. to 2s.; crystals, 39-40, 5⅜d.; 34-35, 5½d. Cresylic, 95%, 1s. 1½d. to 1s. 2d. Anthracene, 40 to 45% A, 1½d. to 1⅝d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quiet, nearest values are:—Beckton, to end of year, £12. 2s. 6d., next year £12. 5s.; Beckton terms, £11. 13s. 9d.; London (outside makes), £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d.; Liverpool ordinary, 11s., and refined, 11s. 3d. Official quotations—Cargoes off coast or due, 11s.; ditto for prompt shipment, 11s. 4½d.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: Standard brands, £96. to £96. 10s. cash, and £88. to £88. 5s. three months. Tin: G.M. quality, £183. 10s. to £184. cash, and £182. to £182. 10s. three months; English, £186. Lead, soft foreign, July delivery, £21. 10s.; first half August £21. 5s.; August, £20. 10s.; September, £20. 7s. 6d.; October, £20. 5s.; English, £22. Spelter, ordinary brands, August, £23. 15s., ex ship; hard, £20., f.o.b. Antimony, £43. to £45.; ore, £10. to £10. 10s. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 16s. Nickel, £175. to £185. Pig-iron closing prices:—Standard, 57s. 6d. cash, and 57s. 7½d. one month; Cleveland, 58s. 10½d. cash, and 57s. 10½d. one month.

FERTILISER MATERIALS.

FRIDAY.

The markets for all fertilisers remain quite featureless, buyers being very apathetic, whilst on the other hand there is no pressure on the part of sellers to effect sales.

Both Tunisian and Florida phosphate rock continue to be firmly held at full prices, though no new business is reported.

Shippers of East Indian bone meal are very firm in their ideas, to-day's quotation, c.i.f. Liverpool, being still £5. 2s. 6d. per ton, nett cash, whilst sellers ask £5. 7s. 6d. to £5. 12s. 6d. per ton, ex store Liverpool. according to quality.

The market for nitrate of soda is without change at 11s. per cwt. for ordinary 95% quality, and 11s. 3d. per cwt. for refined, on spot.

MISCELLANEOUS CHEMICAL MARKET.

THURSDAY.

Business on the whole is fairly good for all descriptions of chemicals. In the alkali trade the works are well employed in all the principal departments. Bleaching powder has been sold heavily over 1908 at and slightly below the price of the current year: spot price stands at £4. 7s. 6d., f.o.r. and f.o.b. Chlorates are unchanged at 3½d. Caustic soda, 70%, £9. 15s., f.o.b. Alkali, 58%, is firm at £4. 10s. per ton, in bags, f.o.r. Soda crystals, 59s. to 60s. per ton, f.o.r. The price of sulphate of copper is rather easier for prompt, at £30. 5s., f.o.b. Saltcake is firm at 37s. 6d. to 40s. per ton, in bulk, f.o.r. Sulphur remains steady at £4. 17s. 6d. for best recovered, f.o.r. There is a general and good demand for acids. Acetate of lime is steady at £12. 10s. for 80%, c.i.f.; acetate of soda, £16. 15s.; white sugar of lead, £32., c.i.f. For acetic acid, pure and technical, there is continued good demand, but sellers are inclined to accept lower prices. White arsenic is steady, at £32. 10s. per ton. Carbonate of potash, 90%, £18. 10s., c.i.f.; caustic potash, 88-90%, £25. per ton. Prussiates of soda and potash are steady at 3¾d. and 6d. per lb. Muriate of ammonia, £24. 16s. per ton.

LIVERPOOL DRYSALTERIES.

THURSDAY

Palm oil in good demand, sales including Lagos at £31. on spot; and hard oils, August-September shipment, £29. 10s. per ton; olive oil steady and inclined to harden. Linseed oil quiet, at 26s. 6d. to 27s. per cwt. for Liverpool makes in export casks. Cottonseed oil in fair demand at 31s. 6d. to 32s. for Liverpool refined in export barrels. Rosin steady on spot, at 12s. for F; 12s. 1½d. for G; and common 10s. 10½d. per cwt. Turpentine steady, at 43s. 3d. per cwt. on spot. Tallow in better demand at 31s. to 34s. per cwt. for North American; South American beef, 34s. 6d., c.i.f. Liverpool; mutton, 35s. 3d. to 35s. 9d. per cwt.; Australian steady. Petroleum: Russian and Roumanian 6⅞d., and American refined at 6⅞d. to 7⅛d. per gallon. Petroleum spirit steady, at 1s. 1½d. to 1s. 3d. per gallon.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

Montreal potashes unchanged, with values nominal. Pearl ash quiet. Bark steady, with little demand. Berries quiet. Logwood and fustic steady, with little offering. Cutch quiet and unchanged. Gum arabic steady. Castor oil at 3⅝d. to 3¾d. for first pressure French; 3½d. for second pressure French; £3. 19s. 6d. for good seconds Calcutta. Gambier quiet: Block steadily held at 19s. to 19s. 6d.; May-June, June-August, and July-August shipments nominally 18s. Cubes on spot, 28s. to 28s. 6d.; July-August shipment 27s. 6d.; and August-September shipment at 27s. 9d. Shellac steady, with TN orange quoted 207s. on spot; American powdered starch, 10s. on spot, and 9s. 6d., c.i.f., for shipment; pearl, 9s. 4½d. on spot, and 9s., c.i.f., for shipment. Cream of tartar, 98%, foreign powder, 81s.; 95%, 79s.; Tartaric acid: English on spot, 11¾d.; foreign, 11d. Citric acid, English, 1s. 11½d.; foreign, 1s. 11¼d.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—The general situation in the trade as regards seed oils shows but little variation upon the same recorded a week ago, and in respect to linseed and cottonseed the markets have remained firm; but in the instance of linseed prices are quoted a trifle lower, and in cottonseed there is good business passing. Amongst the principal imports here to date, as against the same time a year ago, are:—Wheat, 2,228,274 qrs., against 2,263,920 qrs.; flour, 105,792 cwts., against 215,290 cwts.; linseed, 399,790 qrs., against 301,842 qrs.; rapeseed, 59,068 qrs., against 41,030 qrs.; cottonseed, Egyptian, 122,221 tons, against 103,702 tons, other kinds, 95,026 tons, against 78,620 tons; oilcake, 17,277 tons, against 24,796 tons; olive oil, 3,190 tuns, against 2,669 tuns; tar, 2,118 barrels, against 3,412 barrels. Amongst the weekly imports:—Lard, 3,787 cwts.; margarine, 2,532 cwts.; sugar, 32,318 cwts.; colours, 1,928 packages; hemp, 2,110 cwts.; oilcake, 171 tons; wool, 162,842 lbs.; hides, 1,124 cwts. Exports:—Oil, 9,314 cwts.; colours, 2,872 packages; chemicals, 1,972 packages. Linseed is from 3d. to 6d. lower on last week's prices. The quality of Calcutta is better than a year ago, showing a better yield of oil. Linseed oil continues to show signs of weakness, although nominally the same quotation, spot, 24s. 1½d., naked; July-August, 23s. 10½d.; September-December, 22s. 6d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports during the week:—2 tons Germany, 4 Italy, 4 Norway, 3 Turkey; total, 13 tons. Cottonseed has continued firm, with old crop realising more money; July shipment making £8. 5s., and November-January, £7. 3s. 9d. paid. Refined cottonseed oil, 29s. per cwt., spot naked; November-April, 23s. 4½d.; casks £1., and barrels £1. 7s. 6d. per ton extra. Exports for the week:—156 tons Germany, 12 Holland, 3 Norway; total, 171 tons. Turpentine lower, 42s. 4½d., spot; Russian, ditto, 21s. 4½d. Rosins unchanged; olive and castor oils same.

CAKES.—Linseed cakes in good demand with firm market, Cotton cakes unchanged, with few fresh orders.

Digitized by Google

TYNE CHEMICAL REPORT.

THURSDAY.

Chemicals continue unchanged with a fairly steady demand. Caustic soda, 70%, £9. 15s., and 76-77% £10. 10s. per ton. Bleaching powder quiet, at £5. to £5. 5s. per ton. Soda crystals unaltered, at £3. to £3. 2s. 6d. per ton locally. Sulphate of soda firm, at £2. to £2. 2s. 6d. per ton. Sulphur scarce, at £5. to £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett, do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market very strong with a full inquiry, and loading turns for gas and steam coals are fully booked for some little time ahead. Bunker coals are also very firm, and coke keeps steady, with a good demand for blast furnace and foundry qualities.—To-day's quotations:—Best Northumbrian steam, 15s. to 15s. 6d. per ton; second qualities, 14s. 3d. to 14s. 6d. per ton; Northumbrian small coals, 10s. to 10s. 6d. per ton; best gas coals, 14s. 6d. to 15s. per ton; Durham bunker coals, 12s. 9d. to 13s. 6d. per ton; coking coals, 13s. 6d. per ton; household coals, 15s. to 17s. per ton; foundry coke, 24s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

Sulphate of ammonia, Leith and Glasgow deliveries, is in a very quiet condition; inquiry is rather languid, and is almost wholly confined to spot business. Value, however, holds very steadily at £12., f.o.b. Leith, or a fraction over, the cause probably being that makers are well sold forward, and in no urgent need of new business. Sulphate of copper remains uncertain, and, there being no very brisk inquiry, value tends still a little to the losing side. The heavy chemicals are quiet, due partly to the holiday feeling, but prices continue steady at recent figures. Drysalteries are only in moderate demand, but with little or no change in quotations.

Chief prices current are:—Alum (in lump) £5. 5s. to £6. nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s. nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b., Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b., Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16.; and boracic acid, £25., nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream, 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3½d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace) 2¼d., naked, f.a.s., Glasgow; nitrate of soda, 11s. 3d.; paraffin scale, hard, 2d. to 2⅛d.; and soft, 2⅛d. to 2¼d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3¼d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¼d.; ordinary sorts, 6d. and 5¾d., open market prices for spot business at Glasgow and other big centres; ditto (lubricating) 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; and 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42., and £40. less 2½% any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s. nett Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d. prompt, f.o.b. Leith; sulphate of copper, £30. 17s. 6d. to £31., less 5% Liverpool, prompt.

New Companies.

British-Bitumen, Ltd.—Capital £3,000., in 1,950 preference and 1,000 ordinary shares of £1. each and 1,000 deferred shares of 1s. each. This company has been formed to adopt an agreement, the parties to which are not named, to acquire the processes, patents, undertaking, rights, etc., comprised therein, and to carry on the business of miners, bitumen, mineral and metal workers and merchants, etc. No initial public issue. The first directors are T. D. Owen and E. A. Harvey. The holders of the deferred shares may appoint one director. Registered office, 44, Southampton Buildings, Chancery-lane, W.C.

British Carbide Factories, Ltd.—Capital £15,000., in £1. shares. This company has been formed to exploit any chemical and electro-chemical processes, and to carry on the business of manufacturers of and dealers in carbide of calcium, etc. No initial public issue. The first directors are H. Compton, A. Howard and A. Akers; qualification £200. Registered office, 178, Tower Bridge,road, S.E.

J. Harrison Carter, Ltd.—Capital £25,000., in £1 shares (10,000 preference). This company has been formed to take over the business of milling and general engineers, carried on at Dunstable and at 82, Mark-lane, E.C., as J. Harrison Carter, and to adopt an agreement with C. W. Cornish, Ann Carter, G. Carter, T. H. Brinton and D. Hack. No initial public issue. The first directors are G. Carter (managing director) and C. W. Cornish; remuneration of managing director £500. per annum, with a further £20. for every 1% dividend in excess of 5% on the ordinary shares; of C. Cornish £75. per annum, and a further £10. for every 1% dividend in excess of 5% on the ordinary shares. Registered office, Engineering Works, Dunstable.

Naversberg Falum Copper Mines and Works, Ltd.—Capital £100,000., in £1. shares. This company has been formed to acquire certain mines and properties in the province of Dalarne, Kopparbergslan, Central Sweden, and to carry on the business of miners, smelters, refiners, etc. No initial public issue. The first directors are J. Lee and G. C. Eedes. H. Keiller is entitled to act as local consulting director at Falum or elsewhere (or to nominate an approved substitute) subject to holding £5,000. fully paid shares; qualification £200.; remuneration £100. each per annum (£50. extra for the chairman) and 10% of any surplus profits in excess of the amount required to pay 10% on the ordinary shares. The B shares take all the available profits after a non-cumulative dividend of 10% is paid on the A. Registered office, 25-35, New Broad-street, E.C.

New Agglomerates, Ltd.—Capital £5,000., in £1. shares. This company has been formed to acquire and develop an invention for the manufacture of agglomerated fuels and briquettes, to adopt an agreement with C. E. George and A. E. Tavernier, and to carry on the business of colliery proprietors, fuel manufacturers, etc. No initial public issue. The subscribers are to appoint the first directors; qualification 5,000 shares; remuneration £100. each per annum and 10% of the profits available for distribution, divided. Registered office, 63, Tunley-road, Balham, S.W.

Petroleum Development Company, Ltd.—Capital £15,500., in 15,000 ordinary shares of £1. each and 10,000 deferred shares of 1s. each. This company has been formed to acquire any lands, farms, properties, mines, and minerals, bituminous, oil and other properties in Africa or elsewhere, and to carry on the business of petroleum, oil, bitumen, and general miners, refiners, explorers, prospectors, etc. No initial public issue. The subscribers are to appoint the first directors; qualification 100 deferred shares; remuneration £150. each per annum, and 10% of the surplus profits after 20% has been paid on the ordinary shares, divided.

Platinum Corporation, Ltd.—Capital £300,000., in 297,500 ordinary shares of £1. each, and 50,000 deferred shares of 1s. each. This company has been formed to acquire platinum, platinum-gold, and gold concessions in any part of the world, and for the purpose of working the same, to vest them in the Anglo-Russian Platinum Mining Co., Ltd., or any other limited or other company formed to work or capable of working the same under such terms as to the issue to this company of all or part of the shares of such company, or its nominees, or otherwise as may be thought fit,

and to adopt agreements (*a*) between V. I. Shaiduroff, A. I. Shaiduroff, J. A. Barham, J. Seed, H. Claudius Ash, and E. A. Ash; and (*b*) between J. Seed, H. Claudius Ash, and E. A. Ash; and (*c*) between J. Seed, J. A. Barham, H. Claudius Ash, and A. E. Ash; (*d*) between V. I. Shaiduroff, A. I. Shaiduroff, H. Claudius Ash, and H. E. Ash; (*e*) between H. Claudius Ash, A. E. Ash, and J. Seed; (*f*) between H. Claudius Ash, A. E. Ash, and A. D. Schwarz; (*g*) between H. Claudius Ash, A. E. Ash and this company; (*h*) between this company and the Anglo-Russian Platinum Mining Co., Ltd.; and (*i*) between this company and the Share Guarantee Trust, Ltd. Minimum cash subscription 50,000 ordinary shares. The number of directors (other than local directors) is not to be less than two nor more than six. The first are Sir Ernest Clarke, Kt., R. Hewitt, H. Claudius Ash, A. E. Ash and J. Seed; qualification £200.; remuneration £200 each per annum (chairman £100. extra). Directors may not borrow beyond amount of issued capital without sanction of general meeting. Registered office, 4 and 6, Copthall Avenue, E.C.

Simplex Industrial Producer Gas Plants, Ltd.—Capital £600., in £1. shares. This company has been formed to acquire from C. H. Schill the benefit of certain existing inventions and processes relating to gas producer, hydrogen gas and suction gas plants and the working thereof, and to adopt an agreement with C. H. Schill, G. S. Aveyard, A. Denton and B. R. Rowland. No initial public issue. The first directors are B. R. Rowland, A. Denton and G. S. Aveyard; qualification £50. Registered office, 78, King-street, Manchester.

Svano Copper and Sulphur Mines (Norway), Ltd.—Capital £15,000., in 25,000 preference shares and 5,000 deferred shares of 10s. each. This company has been formed to carry on the business indicated by the title. No initial public issue. The subscribers are to appoint the first directors; qualification, 100 preference shares; remuneration £75. each per annum (£25. extra for the chairman). Registered office, Gresham House, Old Broad-street, E.C.

Val de Flores Tin Mining Syndicate, Ltd.—Capital £2,000., in £1. shares. This syndicate has been formed to carry on the business of tin and general miners, explorers, prospectors, metallurgists, dealers in minerals, etc., and to acquire from S. G. Latham, the receiver appointed by Baron Armstrong and A. W. Stallard, trustees under an indenture dated August 11, 1905, executed in their favour by the Tin and Amblygonite Mines, Ltd., and from the trustees certain properties and rights in Spain referred to therein, with a view to further prospecting and developing the same.

Widin Copper Syndicate, Ltd.—Capital £20,000., in £1. shares. This syndicate has been formed to take on option, acquire, examine, protect, develop, maintain and work any leases, claims, concessions, alluvial deposits, mines, minerals, ores, mining rights and properties in any part of the world. No initial public issue. The subscribers are to appoint the first directors; qualification £100. Registered office, 88, Bishopsgate-street Within, E.C.

Societe des Colles et Gelatines Francaises.—Capital £48,000., in 2,400 shares of £20. each. This company has been formed to erect at Chauny, near the St. Gobain works, to make crystal gelatines and osseine; also to acquire the existing works at Nanterre, from Messrs. Roy and Co., and to extend the output there of skin gelatines and thin-sheet gelatines. The directors nominated include Mr. O. Murray. Qualification, 40 shares. London offices: 53, Gracechurch-street, E.C.

LATE ADVERTISEMENT.

ASSISTANT Chemist Wanted; mainly for Inorganic work. Send full particulars, including qualifications, experience, and salary required, to "1,453," c/o *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers)..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Readers will oblige by making their remittances or subscriptions by Postal or Post Office Order, crossed and payable to "Davis Bros."

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

THE GERMAN CHEMICAL TRADE IN 1906.

THE British Consul-General at Frankfort reports that throughout 1906 the German chemical industry was particularly brisk. The demand was so great that the manufacturers could hardly cope with it, and took refuge in contracts with quite exceptional extensions of time for delivery. Nor did the enlargement of existing works prove of any immediate avail, as, owing to the general boom, machinery and apparatus could not be obtained; so that the facility of increased production will only tell in the future. Some members of the industry believe that in various branches the high-water mark has been reached, for the possibility of manufacture and supply has natural limits, while the increase in the cost of raw material and in wages continues. In calculating the value of shares, which to-day stand at a great premium, this opinion is of paramount importance, and contains a warning of possible fluctuations.

The increased cost of raw material was considerable; it was most felt in coal and saltpetre. Wages increased on an average 5 to 10%, yet the prices of finished articles could only be raised somewhat towards the end of the year. They were not in harmony with the increased cost of manufacture, and the consequent shrinkage has to be made good by an intensified working.

The new tariff which came into operation on March 1 renders all comparisons with former years in this industry particularly difficult, if not impossible. The schedule of goods until then in use had distinguished between raw materials and manufactured goods in the chemical and pharmaceutical industries. To-day the main classes are the following:—Mineral and fossil raw materials and mineral oils, prepared wax, compact fat acids, paraffin, etc.; chemical and pharmaceutical products, dyes and dyestuffs. The new scheme has undoubtedly the advantages of a more minute specification, and in deference to the great advance of this industry, introduces a large number of sub-headings, such as nitrates, silicon carbide and other carbides, compressed gases (with the exception of compressed carbonic acid), formalin, etc. The need of such sub-divisions becomes clear from the fact that in 1905 the general group—not otherwise specified—represented an export value of 29,600,000 marks, and an import value of 9,400,000 marks. The new schedule still contains a general group, namely, chemical products for medicinal use, the export of which amounted to 5,100,000 marks during the ten months of 1906 in which the tariff was in operation. The continuance of some such general group was considered a necessity, because the chemical items for medicinal use are subject to great variations and changes. As many of the older existing groups have been rearranged, it is not possible to prove from statistical comparisons with former

Digitized by Google

years, which individual items have been chiefly affected by the new treaties. Yet generally it is calculated that with the exception of a few articles the chemical industry has, during the first year of the new tariff, been able to increase its sales.

While the import of raw materials has been tremendously increased, the export of manufactured articles has either maintained the exceptional figures of 1905, or even surpassed them, as in the case of organic dyes. Certainly the success of the year is assigned to the world's boom, and not to any advantages which the chemical industry has gained from the new treaties. There is, indeed, a consensus of opinion that the German chemical industry has become seriously handicapped in its export, at least to certain countries—*e.g.*, France, Austria-Hungary, and Russia. In the case of Austria-Hungary, for instance, where the customs regulations are enforced with particular rigour, the duty upon the products of the German coal-tar industry has, roughly speaking, been increased twelvefold. In both Russia and Austria-Hungary, branch factories have been established so that an intensified working abroad of German capital, but not of German labour, will be the result. In the treaty with Switzerland, the Federal Government undertook to extend the benefits of its patent laws to chemical produce; but the Bill at present under discussion is condemned by the German chemical industry. Manufacturers complain that, at the conclusion of the commercial treaty, German representatives used terms which were too wide, and which may possibly make this concession to Germany illusory. There was also in the chemical world much dissatisfaction because the new commercial treaty with the United States was delayed. Under the existing customs tariff, the United States are rapidly developing a coal-tar colour industry of their own, and if the new treaty brings no change in this respect, German branch factories in the United States will be the only means of preserving what is left of the market. In the meantime the chemical industry at home is strengthening its position by means of concentration. A collapse of prices, more especially in the colour industry, had suggested some understanding between the leading manufacturers. The lowest possible prices had been reached, together with the cheapest possible individual production. A further reduction in the cost of manufacture could only be attained by means of combination, simplifying the organisation of the existing works, consolidating identical branches of manufacture, reducing the expenses in connection with sales, and abolishing such incidental expenses of competition as advertisements, etc. The patent protection had proved of little avail. Any patent granted had stimulated research in competitive establishments, and the competition resulting from an alternative mode of production reduced the value of the manufactured article below cost price. Thus it is said that one of the direct inducements for combination was offered by the manufacture of synthetic indigo; in fact, as far as this article is concerned, an understanding has been arrived at, not only within certain groups, but between the leading groups themselves; and this understanding is pointed to as possibly the first step towards a gigantic German chemical trust.

The British Consul-General observes that to-day the use of natural indigo has been practically discontinued in Germany and Austria-Hungary; and even France, which has long opposed the use of this German product, now shows a marked preference for it. Russia, Turkey, Egypt, and North America have so far remained the most faithful customers for natural indigo, probably because the sale in those countries is controlled by middlemen, who find the sale of the artificial dye less profitable, because it has a definite market price. There is no doubt that natural indigo has been more rapidly ousted than even the most hopeful manufacturers of the artificial article had anticipated. The values and quantities of import and export of indigo in 1905-06 are given below:—

1905.

	Imports.		Exports.	
	Quantity in 1,000 Tons.	Value in 1,000,000 Marks.	Quantity in 1,000 Tons.	Value in 1,000,000 Marks.
Indigo	0.2	0.1	11.2	25.7
Aniline and other tar dyestuffs	1.7	4.8	36.6	100.6
Alizarin	..	0.1	9.3	15.5
Total	..	5.0	..	141.8

1906.

	Imports.		Exports.	
	Quantity in 1,000 Tons.	Value in 1,000,000 Marks.	Quantity in 1,000 Tons.	Value in 1,000,000 Marks.
Indigo	0.1	0.1	12.7	29.3
Aniline and other tar dyestuffs	2.0	5.5	52.4	110.6
Anthracin dyes (10 months)	..	0.1	4.6	12.8
Alizarin (red)	..	..	7.2	9.8
Total		5.7	..	168.5

From this table it follows incidentally that the value of the excess export of artificial dyestuffs has risen in 1906 against 1905, by 27,000,000 marks.

The following are the dividends of the more important chemical factories:—

	1903. Per cent.	1904. Per cent.	1905. Per cent.	1906. Per cent.
Badische Anilin und Soda Fab.	26	24	27	30
Chem. Fab. vorm. Weiler ter Meer (Uerdingen)	10	8	8	10
Verein chem. Fab. Mannheim.	..	16	19	20
Chem. Fab. Buckau, Magdeburg.	..	..	10	12
Chem. Fab. Electron, Greisheim.	12	12	12	12
Farbwerke vorm. Meister, Lucius and Brüning ..	20	20	24	30
Deutsche Gold und Silber-scheide-Anstalt, Frankfurt-on-Maine		18	22	..
Chem. Werke Albert, Biebrich.	15	18	19	22½
Friedrich Bayer u. Co., Elberfeld	25	30	33	36

Borax Consolidated.—An interim dividend of 5s. per share for the quarter ended March 31 is announced, being at the rate of 10% per annum.

Soap Trade Litigation.—The *Yorkshire Post* says:—"The settlement of the actions brought by Messrs. Joseph Watson and Sons Ltd., soap manufacturers, Leeds, against the Associated Newspapers—and concurrently the dropping of the actions against the *Leeds and Yorkshire Mercury* and the *Glasgow Daily Mail and Record*—involves the unreserved withdrawal of every imputation against Messrs. Watson and the payment to them of very heavy damages. The parties to the settlement are pledged not to divulge the sum agreed upon, and inquiries failed to elicit anything more definite than the statement, made on high authority, that the aggregate amount of compensation to be paid to Messrs. Watson is considerably more than the £50,000. accepted by Messrs. Lever Bros. It is stated that the settlement was arrived at in a most amicable spirit.

THE BRITISH ASSOCIATION.

LEICESTER MEETING.

THE seventy-seventh annual meeting of the British Association was opened on Wednesday last, at Leicester. The attendance at the meeting was about 1,500, compared with 2,000 at York last year.

On Wednesday afternoon, at a meeting of the Council, the draft report for 1906-7 was approved. It was announced that Mr. Francis Darwin, F.R.S., would be President of the Association next year. The President-Elect is a son of Charles Darwin; he assisted his father largely in his experiments, and is the author of the standard "Life and Letters." He is now Reader in Botany at Cambridge.

THE PRESIDENT'S ADDRESS.

On Wednesday evening, in the Opera House, the President, Sir David Gill, K.C.B., LL.D., D.Sc., F.R.S., etc., late H.M. Astronomer at the Cape, delivered his inaugural address.

The President said:—To-night, for the first time in its history the British Association meets in the ancient city of Leicester; and it now becomes my privilege to convey to you, Mr. Mayor, and to the citizens generally, an expression of our thanks for your kind invitation and for the hospitable reception which you have accorded to us.

Here in Leicester, and last year in York, the Association has followed its usual custom of holding its annual meeting somewhere in the United Kingdom; but in 1905 the meeting was, as you know, held in South Africa. Now, having myself only recently come from the Cape, I wish to take this opportunity of saying that this Southern visit of the Association has, in my opinion, been productive of much good: wider interest in science has been created amongst colonists, juster estimates of the country and its problems have been formed on the part of the visitors, and personal friendships and interchange of ideas between thinking men in South Africa and at home have arisen which cannot fail to have a beneficial influence on the social, political, and scientific relations between these colonies and the mother country. We may confidently look for like results from the proposed visit of the Association to Canada in 1909.

One is tempted to take advantage of the wide publicity given to words from this Chair to speak at large in the cause of science, to insist upon the necessity for its wider inclusion in the education of our youth and the devotion of a larger measure of the public funds in aid of scientific research; to point to the supreme value of science as a means for the culture of those faculties which in man promote that knowledge which is power; and to show how dependent is the progress of a nation upon its scientific attainment.

But in recent years these truths have been prominently brought before the Association from this Chair; they have been exhaustively demonstrated by Sir William Huggins from the Chair of the Royal Society, and now a special guild (The British Science Guild) exists for their enforcement upon the mind of the nation.

These considerations appear to warrant me in following the healthy custom of so many previous Presidents—*viz.*, of confining their remarks mainly to those departments of science with which the labours of their lives have been chiefly associated.

Dealing first with the "Science of Measurement," the President continued: Lord Kelvin, in 1871, made a statement from the Presidential Chair of the Association at Edinburgh as follows: "Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than the looking for something new. But nearly all the grandest discoveries of science have been the reward of accurate measurement and patient, long-continued labour in the minute sifting of numerical results."

Besides the instances quoted by Lord Kelvin in support of that statement, we have perhaps as remarkable and typical an exemplification as any in Lord Rayleigh's long-continued work on the density of nitrogen, which led him to the discovery of argon. We shall see presently that, true as Lord Kelvin's words are in regard to most fields of science, they are specially applicable as a guide in astronomy.

One of Clerk Maxwell's lectures in the Natural Philosophy Class at Marischal College, Aberdeen, when I was a student under him there, in the year 1859, ran somewhat as follows:—

"A standard, as it is at present understood in England, is not a real standard at all; it is a rod of metal with lines ruled upon it to mark the yard, and it is kept somewhere in the House of Commons. If the House of Commons catches fire there may be an end of your standard. A copy of a standard can never be a real standard, because all the work of human hands is liable to error. Besides, will your so-called standard remain of a constant length? It certainly will change by temperature, it probably will change by age (that is, by the rearrangement or settling down of its component molecules), and I am not sure if it does not change according to the azimuth in which it is used. At all events, you must see that it is a very impractical standard—impractical because, if, for example, any one of you went to Mars or Jupiter, and the people there asked you what was your standard of measure, you could not tell them, you could not reproduce it, and you would feel very foolish. Whereas, if you told any capable physicist in Mars or Jupiter that you used some natural invariable standard, such as the wave-length of the D-line of sodium vapour, he would be able to reproduce your yard or your inch, provided that you could tell him how many of such wave-lengths there were in your yard or your inch, and your standard would be available anywhere in the universe where sodium is found."

That was the whimsical way in which Clerk Maxwell used to impress great principles upon us. We all laughed before we understood; then some of us understood and remembered.

Now the scientific world has practically adopted Maxwell's form of natural standard. It is true that it names that standard the metre; but that standard is not one-millionth of the Earth's quadrant in length, as it was intended to be; it is merely a certain piece of metal approximately of that length. It is true that the length of that piece of metal has been reproduced with more precision, and is known with higher accuracy in terms of many secondary standards, than is the length of any other standard in the world; but it is, after all, liable to destruction and to possible secular change of length. For these reasons it cannot be scientifically described otherwise than as a piece of metal whose length at 0° C. at the epoch A.D. 1906 is = 1,553,164 times the wave-length of the red line of the spectrum of cadmium when the latter is observed in dry air at the temperature of 15° C. of the normal hydrogen-scale at a pressure of 760 mm. of mercury at 0° C. This determination, recently made by methods based on the interference of light-waves and carried out by MM. Perot and Fabry at the International Bureau of Weights and Measures, constitutes a real advance in scientific metrology. The result appears to be reliable within one ten-millionth part of the metre. The length of the metre, in terms of the wave-length of the red line in the spectrum of cadmium, had been determined in 1892 by Michelson's method, with a mean result in almost exact accordance with that just quoted for the comparisons of 1906; but this agreement (within one part in ten millions) is due in some degree to chance, as the uncertainty of the earlier determination was probably ten times greater than the difference between the two independent results of 1892 and 1906.

We owe to M. Guillaume, of the same International Bureau, the discovery of the remarkable properties of the alloys of nickel and steel, and from the point of view of exact measurement the specially valuable discovery of the properties of that alloy which we now call "invar." He has developed methods for treatment of wires made from this alloy which render more permanent the arrangement of their constituent molecules. Thus these wires, with their attached scales, may, for considerable periods of time and under circumstances of careful treatment, be regarded as nearly invariable standards. With proper precautions, we have found at the Cape of Good Hope that these wires can be used for the measurement of base lines of the highest geodetic precision with all the accuracy attainable by the older and most costly forms of apparatus; whilst with the new apparatus a base of 20 kilometres can be measured in less time and for less cost than one of a single kilometre with the older forms of measurement.

The President then gave details regarding the progress recently made with the topographic survey of the great African arc of meridian, and before leaving the subject he urged his Majesty's Government to assist the various learned societies in providing funds to carry out this great work.

Continuing, Sir David Gill dealt in an interesting and very complete manner with the developments that have taken place in the various branches of astronomy, the bare outlines of which, however, can only begiven here. The exact measurement of the great fundamental unit of astronomy—the solar parallax—has made great progress. Observations of the transits of Venus have given but uncertain data, and more accurate knowledge is now to be gained from the measurement of angular distances between stars of minor planets. The recently discovered planet

Digitized by Google

Eros afforded a most unexpected opportunity of redetermining this constant, and in 1931 Eros will approach the earth within one-sixth part of the Sun's mean distance, when it is hoped that the solar parallax will be ascertained within one ten-thousandth part of its amount. It is suggested that a congress of astronomers should assemble in 1908, to consider what steps should be taken with reference to this important opposition of Eros in 1931.

The subject of star-catalogues of precision was treated at some length, and their use in determining the dynamical conditions of the universe, and something of the velocity and direction of our solar system through space, was carefully explained. It was also pointed out that the value of a star-catalogue of precision for the present purposes of cosmic research varies as the square of its age and the square of its accuracy.

In comparing the progress of astronomy in the Northern and Southern Hemispheres, the President made it the occasion of describing the growth of the Cape of Good Hope Observatory, and he treated in a terse and lucid manner the various historical accounts of the Southern Cross.

Perhaps the most interesting portion of the address was that dealing with the constitution of the Universe, in which was considered a statement by Tobias Mayer, in 1760. "If the Sun, and with it the planets and the Earth which we inhabit, tended to move directly towards some point in the heavens, all the stars scattered in that region would seem to gradually move apart from each other, whilst those in the opposite quarter would mutually approach each other. In the same manner one who walks in the forest sees the trees which are before him separate, and those that he leaves behind him approach each other." Sir Wm. Herschel, in 1783, it was pointed out, made the first attempt to apply with any measure of success Mayer's notion, and he concluded that the Sun's motion in space is nearly in the direction of the star λ Herculis, and that 80% of the apparent motions of fourteen stars could be assigned to this common origin. This idea, however, conveys but a portion of the truth, as it takes no account of the independent motion of the stars themselves. This at once creates a new difficulty, *viz.*, that of defining an absolute *locus* in space. The human mind may exhaust itself in the effort, but it can never solve the problem. We can imagine, for example, the position of the Sun at any moment to be defined with reference to any number of surrounding stars, but by no effort of imagination can we devise means of defining the *absolute* position of a body in space without reference to surrounding material objects. If, therefore, the referring objects have unknown motions of their own, the rigour of the definition is lost. If, however, the peculiar motions of the stars be arranged at random, they may be considered zero in the mean of a considerable number of them. It is then possible to find a common apex for the solar motion as shall leave the residual peculiar motions of the stars under discussion to be in the mean = zero. That is to say, we refer the motion of the Sun in space to the centre of gravity of all the stars considered in the discussion, and regard that centre of gravity as immovable in space. This subject leads directly to the study of stellar parallax, and it was pointed out that what we specially need is not to ascertain the parallax of the individual star, but the mean parallax of a particular group or class of stars—in other words, the centre of gravity of any extensive group of stars.

Here the brilliant work of Professor Kapteyn, of Groningen, on the determination of stellar parallax, was magnificently described. Adopting an approximate position of the apex of the solar motion, Kapteyn resolved the observed proper motions of the Bradley stars into two components, *viz.*, one in the plane of the great circle passing through the star and the apex of the other at right angles to that plane. From the former the mean parallactic motion of the group is derived, and from the combination of the two components the relation of velocity of the Sun's motion to that of the mean velocity of the stars of the group. It was shown that the true value of the Sun's velocity lies between 18 to 20 kilometres per second.

Another extremely interesting portion of the address was that on the density of stellar distribution at different distances from our Sun. Starting from the Sun, the star-density (*i.e.*, the number of stars per unit volume of space) is pretty constant till a distance is reached of some 200 light-years. Thence the density gradually diminishes till, at about 2,500 light-years, it is only about one-fifth of the density in the neighbourhood of the Sun.

The President next considered the question of the future course of astronomical research, and in conclusion said :—"The ancient philosophers were confident in the adequacy of their intellectual powers alone to determine the laws of human thought and regulate the actions of their fellow men, and they did not hesitate to employ the same unsupported means for the solution of the riddle of the universe. Every school of philosophy was agreed that some object which they could see was a fixed centre of the universe, and the battle was fought as to what the centre was. The absence of facts, their entire ignorance of methods of exact measurement, did not daunt them, and the question furnished them a subject of dispute and fruitless occupation for twenty-five centuries. But astronomers now recognise that Bradley's meridian observations at Greenwich, made only 150 years ago, have contributed more to the advancement of sidereal astronomy than all the speculations of preceding centuries. They have learned the lesson that human knowledge in the slowly developing phenomena of sidereal astronomy must be content to progress by the accumulating labours of successive generations of men ; that progress will be measured for generations yet to come more by the amount of honest, well-directed, and systematically discussed observation than by the most brilliant speculation ; and that, in observation, concentrated systematic effort on a special thoughtfully selected problem will be of more avail than the most brilliant but disconnected work. By these means we shall learn more and more of the wonders that surround us, and recognise our limitations when measurement and facts fail us.

Huggins's spectroscope has shown that many nebulæ are not stars at all ; that many well-condensed nebulæ, as well as vast patches of nebulous light in the sky, are but inchoate masses of luminous gas. Evidence upon evidence has accumulated to show that such nebulæ consist of the matter out of which stars (*i.e.*, suns) have been and are being evolved. The different types of star spectra form such a complete and gradual sequence (from simple spectra resembling those of nebulæ onwards through types of gradually increasing complexity) as to suggest that we have before us, written in the cryptograms of these spectra, the complete story of the evolution of suns from the inchoate nebula onwards to the most active sun (like our own), and then downward to the almost heatless and invisible ball. The period during which human life has existed on our globe is probably too short—even if our first parents had begun the work—to afford observational proof of such a cycle of change in any particular star ; but the fact of such evolution, with the evidence before us, can hardly be doubted. I most fully believe that, when the modifications of terrestrial spectra under sufficiently varied conditions of temperature, pressure, and environment have been further studied, this conclusion will be greatly strengthened. But in this study we must have regard also to the spectra of the stars themselves. The stars are the crucibles of the Creator. There we see matter under conditions of temperature and pressure and environment, the variety of which we cannot hope to emulate in our laboratories, and on a scale of magnitude beside which the proportion of our greatest experiment is less than that of the drop to the ocean. The spectroscopic astronomer has to thank the physicist and the chemist for the foundation of his science, but the time is coming—we almost see it now—when the astronomer will repay the debt by wide-reaching contributions to the very fundamenta of chemical science.

"By patient, long-continued labour in the minute sifting of numerical results, the grand discovery has been made that a great part of space, so far as we have visible knowledge of it, is occupied by two majestic streams of stars travelling in opposite directions. Accurate and minute measurement has given us some certain knowledge as to the distances of the stars within a certain limited portion of space, and in the cryptograms of their spectra has been deciphered the amazing truth that the stars of both streams are alike in design, alike in chemical constitution, and alike in process of development.

"But whence has come the two vast streams of matter out of which have been evolved these stars that now move through space in such majestic procession ?

"The hundreds of millions of stars that comprise these streams, are they the sole ponderable occupants of space ? However vast may be the system to which they belong, that system itself is but a speck in illimitable space ; may it not be but one of millions of such systems that pervade the infinite ? We do not know. 'Canst thou by searching find out God ? canst thou find out then Almighty unto perfection ?'"

The presidential address in Section B. (Chemistry), and also special abstracts of other Sectional addresses, will appear in our next issue.

THE INSTITUTE OF CHEMISTRY.

JULY EXAMINATIONS, 1907.

THE following were the papers set at the Intermediate and Final (A.I.C.) Examinations of the Institute :—

Intermediate Examination.

General and Theoretical Chemistry.

Tuesday, July 2nd.—Four questions to be answered. (1) Give the formula of every "per" acid which you know and of a salt of each acid, indicating modes of preparation and properties in each case. (2) Calculate the heat of combination of Ca and O from the equations :

(1) $CaO + 2HCl = CaCl_2 + H_2O + 52.7$ Cal.
(2) $Ca + Cl_2 = CaCl_2 + 169.8$ Cal.
(3) $H_2 + O = H_2O + 57.9$ Cal.
(4) $H + Cl = HCl + 22.0$ Cal.

Mention a condition which must be identical in equations (1) and (3) in order that the calculation may give a correct result. (3) How is fluorine prepared? In what chemical characteristic does it differ from other members of the halogen group? (4) What is the ordinary source of cadmium? Compare its chemical and physical properties with those of lead and zinc. (5) Mention any substances which can be obtained in the electric (not electrolytic) furnace and by no other means. What are the characteristics which these substances have in common? (6) What reactions take place when a solution of sodium chloride is electrolysed between unattackable electrodes (*a*) with and (*b*) without a diaphragm. In the latter case, what effect (if any) is due to the temperature of the electrolyte? Give equations as far as possible.

Four questions to be answered. (1) State the principal methods of preparing amines of both the fatty and the aromatic series. Describe the actions of nitrous acid on those compounds, or their salts, and indicate the uses of the products thus obtained from primary aromatic amines. (2) Describe the characteristic properties of beryllium and its compounds, and compare and contrast these with the corresponding compounds of aluminium. (3) From what natural sources can cinnamic acid be obtained, and how is it prepared synthetically? Explain fully how you would proceed to elucidate the constitution of the acid. Trace the steps in the process by which cinnamic acid can be converted into indigotin. (4) Describe the various applications of the chlorides of phosphorus, aluminium, iron, and tin respectively in the preparation or investigation of carbon compounds. (5) Give a full description of the principal fermentation processes which are of technical importance for the preparation of organic substances. (6) Write a brief account (*a*) of the principal methods of liquefying refractory gases, stating clearly the principles upon which they are based, and (*b*) of the investigations which have been made on chemical action at low temperatures.

Wednesday, July 3rd.—(1) Determine the total chlorine and the free hydrochloric acid in the sample, A, which is a solution of sodium chloride in dilute hydrochloric acid. (2) Fully identify the given compound, B, and leave a purified specimen of at least one derivative obtained in the course of the investigation. (Ethyl benzoate, ethyl succinate, methyl salicylate ; one to each candidate.)

Thursday, July 4th.—(1) Determine the percentage of nitrogen in the given compound by Kjeldahl's process. Investigate the manner in which the nitrogen is combined, and leave specimens of any derivatives which you can obtain. (Oxamide, oxanilide, oxamethane ; one to each candidate.) (2) Identify by the spectroscope the two metals in the given mixture. (Lithium and calcium carbonates, lithium and strontium carbonates, lithium and barium carbonates ; one to each candidate.)

Friday, July 5th.—(1) Make a complete qualitative analysis of the given alloy. (Copper, lead, tin, and nickel.) (2) Estimate the weight of copper in 100 c.c. of the given solution : (i.) by a gravimetric method, and (ii.) volumetrically, by the thiosulphate method.

Final Examinations for the Associateship.

Branch "A."—Mineral Chemistry.

Tuesday, July 9th.—Analyse the sample of carborundum.

Wednesday, July 10th.—From the lead nitrate provided, prepare specimens of (*a*) pure oxygen, (*b*) pure nitrogen peroxide, and (*c*) pure nitrogen.

Thursday, July 11th.—Determine the silica and lead oxide in the sample of glass.

Friday, July 12th.—Determine the phosphorus in the sample of phosphor tin.

Branch "B"—Metallurgical Chemistry.

(1) Determine the percentage of copper and silver in the given sample of copper antimony silver ore, or, take a cooling curve of the given alloy and determine its solidifying point. (*If this exercise be chosen it must be finished on the first day.*) (2) Examine and report upon the sample of pig iron submitted to you with reference to its suitability for manufacture of steel in the acid open hearth process.

Thursday and Friday, July 11th and 12th.—(1) Examine and report upon the sample of coal submitted to you as to its suitability for the manufacture of coke for blast furnace purposes. (2) Determine the percentage of tin, antimony, and copper in the given sample of white metal, or, examine microscopically the samples of copper tin alloy, and steel submitted to you, and describe in detail their structure. Heat the sample of steel for 20 minutes at a temperature of 780° C., and cool slowly. Prepare a low and high power photomicrograph of the steel after heating and slow cooling.

No candidate was examined in Branch "C" (Physical Chemistry.)

Branch "D."—Organic Chemistry.

Tuesday, July 9th.—(1) Determine by Kjeldahl's process the percentage of nitrogen in the given substance. (Succinimide.) (2) Investigate the character of the substance as fully as possible, and prepare specimens of at least two crystalline derivatives.

Wednesday, July 10th.—(1) Examine the methyl alcohol, A, determine the proportion of any impurity found, and prepare a specimen of the pure alcohol. (2) Identify the ingredients of the mixture B, and ascertain approximately the proportions in which they are present. (Methyl oxalate and oxanilide.)

Thursday, July 11th.—(1) Prepare from the given salt a specimen of its base, and determine its solubility in water at 100°. (2) Prepare from the base specimens of characteristic derivatives other than salts. (3) Identify the salt, and estimate the percentage of the acid radicle. (Benzidine sulphate).

Friday, July 12th.—(1) Determine, by the cryoscopic method, the molecular weight of the given substance. (Amygdalin.) (2) Investigate the substance as fully as time will permit. Leave on your bench specimens of any products you obtain.

Branch "E."—The Analysis of Food and Drugs, and of Water.

Monday, July 1st.—Therapeutics and Pharmacology.—(1) Write a full description of the chief active substance present in belladonna leaves, and give the pharmacopœal method for its extraction. Enumerate its official preparations and their full medicinal doses. (2) Compare the pharmacological characters of the perchloride and subchloride of mercury. Discuss the practical therapeutic employment of these salts. (3) Enumerate the drugs which are commonly administered by injection under the skin. Give the strength of the solutions so used, and mention in each case the full dose for injection. (4) What indications pointing to the consumption of the following drugs can be obtained by an examination of the urine :—Chloral hydrate, silicin, phenol.

Oral and practical examination in the recognition of chemicals and drugs.

Microscopy. (1) The fabric, A, is seen to be smeared with adherent matter. Examine this microscopically and report upon it. Leave upon your bench the prepared slides you obtain from it. (2) B and C are food substances in powdered form. Make a microscopic examination of each and report upon the result. (3) Make a clean permanent preparation of starch granules from the potato provided. Leave the prepared slide upon your bench. (4) Identify the objects on the slides 1 to 6.

Tuesday, July 2nd.—(1) Examine the sample of milk as if submitted to you under the Sale of Food and Drugs Acts, using the official form supplied to you. Determine the fat by at least two different methods. (2) Examine the sample of crude carbolic acid with a view to ascertaining if it complies with the requirements of the following specification :—"The sample shall be free from tar oils, contain not less than 95% by volume, of tar acids and not more than 5% of water. It shall be wholly soluble in caustic soda of sp. gr. 1.07."

Wednesday, July 3rd.—(1) Examine and report upon the sample of jam with reference to the proportions of cane and

Digitized by Google

invert sugar respectively, and to the presence of foreign fruits. (2) Ascertain if the sample of Pil. Hydrarg. complies with the requirements of the British Pharmacopœia.

Thursday, July 4th.—(1) Determine the poison in the given specimen of stomach contents. (Phosphorus.) (2) Make such determinations (higher alcohols excepted) on the sample of brandy as will enable you to express an opinion as to its genuineness. (This exercise to be completed to-morrow.)

Friday, July 5th.—(1) Complete the examination of the brandy. (2) Make a qualitative examination of the sample of baking powder, and estimate the amount of available carbonic acid.

The candidate is required to construct the apparatus necessary for this determination.

(3) Examine and report on the genuineness, or otherwise, of the sample of powdered drug. (Gentian root.)

Reports of Companies.

THE ZINC CORPORATION.

On Tuesday last a special meeting of shareholders of the Zinc Corporation was held, Mr. F. A. Govett (chairman) presiding. The Chairman said they had met to consider the position of the company in order to determine what funds should be raised to carry their business to a successful conclusion. They had borne a burden of anxieties and responsibilities on their shoulders. It had been a horrible position made even worse by the correspondence they had received. He had suffered under his position, and it was a relief to meet them at this meeting. He had done, and would do, honestly, honourably, and earnestly, his best in their service. Some shareholders thought the starting-point of reform would be a clean sweep of the board, but he thought a clean sweep of the board might mean a complete breakdown. They now had a single control in England, instead of the board being halved at the end of a long cable, and their managers were their sole representatives in Australia. This he regarded as vital to the proper management of their affairs. When the company was formed there were four or five rival processes for working, and they adopted the mineral separation process. All the processes were now the same, and they had decided to instal sixteen units of the Elmore plant. They wanted money to do this, and they proposed to create 182,000 preference shares of £1. each. These sixteen units would be half the mill, and would cost £50,000. to construct. They had £275,000. worth of assets, against which they had £30,000. worth of debts. The immediate objects of the increase of the capital were the completion of the construction of half of the new plant, the repayment of the £30,000. temporary loan, and £22,500. every three months for tailings. He concluded by formally moving that the capital be increased to £682,000. by the creation of 182,000 preference shares of £1. each, that the 500,000 shares in the existing capital be called ordinary shares, and that the preference shares be offered in the first place to the shareholders pro rata in the proportion of two new shares to each five ordinary shares.

Several shareholders put questions, and on the resolutions being put to the vote they were carried by a large majority.

BRYANT AND MAY, LTD.

The report states that the net profits for the year to June 30 amounted to £128,423., and the directors declare the full dividend on the preferred shares, and dividends amounting to 6% for the year on the deferred shares. The sum of £25,000. is placed to general reserve, and £12,223. is carried forward. The board are of opinion that the Californian property, which is owned jointly with the Diamond Match Company of America, may be properly formed into a separate company, and it is hoped that a proposal with that object will be submitted in the next few months.

ARIZONA COPPER COMPANY.

The half-yearly report to March 31 states that the surplus after payment of preferential dividends, subject to capital expenditure, redemption of debt, and contingencies is £235,913. The amount brought forward makes the available surplus £247,421., out of which the directors have resolved to pay interim dividends of 2s. 3d. per share free of tax on the preferred ordinary and deferred ordinary shares, leaving a balance of £76,433. to be carried forward. The report states that the results were seriously affected by the flood in December last, and the bursting of a neighbouring dam. The actual amount expended in repairing the damage done exceeded £30,000., in addition to which there was a much larger amount of indirect loss, the operations of the company being suspended for nearly a month. The output for the half-year was also affected by the prevailing labour conditions.

ZAPIGA NITRATE CO., LTD.

The report states that the gross trading profit for the year is £15,151., and, after providing for the statutory reserve, the deduction of the usual general charges, loss on exchange, debenture interest and income tax, there remains a balance of £9,554. An interim dividend of 1s. per share was paid on October 1st, 1906, absorbing £4,000., and it is now proposed to carry forward the balance of £5,554. The earnings for the period under review have been affected, in common with other nitrate concerns, by the abnormal cost of stores and the rise in wages. It has been found necessary to spend £13,277. in additions to the plant in order to obtain the most economical results from the raw material treated.

BRITISH OIL AND CAKE MILLS, LTD.

The interim report states that the anticipation of satisfactory trading held out at the last general meeting has been realised. The net trading profit amounts to £93,708., against £62,251. for the corresponding six months in 1906. A further encouraging feature is the continued increase in the volume of the company's trade. The board is sanguine that it may be able at the end of this year to increase the reserves.

Continental Notes.

THE *Chemische Industrie* for July 1 contains the annual report for 1906 of the inspectors of the Trade Guild for the Chemical Trade of Germany, and, as usual, there are given descriptions and illustrations of a number of new safety appliances for use in chemical works. These include appliances for emptying and filling vessels with liquefied chlorine and other compressed gases, for operating valves from a distance, a protective shield for acid cocks, a soap press, and an arrangement for the pipes of compressed air reservoirs. The number of accidents showed an increase over the previous year, amounting to 11,169 as compared with 11,010; 1,744 of these ranked for compensation, and 129 persons were killed. Several accidents happened through the splitting of the fly-wheels of steam engines which had attained too high a speed in consequence of the failure of the governor, which in each case was driven by a single belt. This belt came off and caused the accidents, one of which was a fatal one. It is now recommended that there shall in future be a second independent belt to drive the governor; the belts are to be examined every day; and there is to be a valve which will not pass through more than the maximum amount of steam that the engine can safely take. Under the heading of explosives, particulars are given of the disastrous explosion at the Roburite factory at Witten, which caused the deaths of 39 persons. No definite conclusions have been arrived at as to the cause of the catastrophe. It will be remembered that a fire first broke out in the mixing room, which after a short time exploded and set fire to many of the other buildings in the factory, amongst others the sheds in which the raw materials, ammonium nitrate, trinitrotoluene, etc., were stored. The quantity of these materials was very considerable, and after a time they also exploded with terrific violence. Details will be found of a number of other accidents.

In the *Elektrochemische Zeitschrift* for July there appears a paper by Wiechmann, describing a new primary electric cell, which he claims to possess special advantages. It consists of plates of metallic zinc and oxide of copper in a saturated solution of caustic soda. When a current passes, the zinc is oxidised and the copper oxide reduced, sodium dioxide being formed as an intermediate product, which, however, soon passes its oxygen on to the zinc. The consumption of zinc is said to be little more than the theoretical.

In the same issue there are instalments of articles on the production of ozone, the metallurgy of tin, and the electrometallurgy of iron.

The *Zentralblatt für die Kunstdunger-Industrie* for June 7 contains an article by Dr. Ehrenburg on nitrification and its function in agriculture. It is true that plants are capable of taking up ammonia compounds directly, and utilising them as food stuffs, but in soil containing lime the roots will suffer through the liberation of ammonia, which exerts a caustic action

Digitized by Google

on them. In neutral soil, on the other hand, the plants are injured by the acid action of ammonia salts, except in the case of plants that have a special liking for acid. When it is desired to manure with ammonia salts, it is therefore necessary to encourage the bacteria which convert them first into nitrites and then into nitrates,

In the same issue there is an account of experiments carried out by J. Sebelien, to ascertain the comparative value of the various nitrogenous manures. The effectiveness of these is very different in different cases.

In the issue for June 21, Dr. M. Weitz brings forward some criticisms of the statements that have been made by Professors Frank and Birkeland in advocating the artificial production of nitrogen compounds from atmospheric nitrogen. He denies that there is any danger of the deposits of saltpetre giving out in about forty years' time. On the contrary, with the new fields that have recently been discovered there is no fear of the supply falling off before the end of the present century. He points out various disadvantages of "lime-nitrogen," such as its property of absorbing large quantities of water from the air. It is true that sodium nitrate is also somewhat hygroscopic, but not to such an extent as to prevent its use for so many chemical and agricultural purposes. In spite of all that has been said and written about the utilisation of the nitrogen of the air, very little calcium cyanamide or calcium nitrate has yet been placed on the market.

There is also a paper by Dr. M. Hoffmann, on the utilisation of the carcases of animals, which at present are frequently wasted.

Indian Notes.

MARKET movements (Calcutta, 4th July) are reported as under:—

Borax.—Offerings are very small, and prices are Rs.14.12. to Rs.15.8. per bazar maund weight, loose, for quick delivery.

Castor oil cake.—Owing to the continued lightness of export orders, prices have given way to Rs.5.14. to Rs.6.2. per bag of two maunds, f.o.b., for short-date shipment. Offerings are low.

Cocoanut oil.—Prices are maintained. Prices are Rs.20.8. to Rs.21.8. per bazar maund weight, loose. Stocks are light, and supplies continue inadequate, owing to dear prices.

Beeswax has continued in strong request for Singapore and Straits Settlements, at Rs.81.0. to Rs.88.0 for locally refined white sorts, and Rs.71.0. to Rs.85.0. for raw, per bazar maund weight, loose. Stocks and supplies are very small.

Castor oil is firm, and crushers are very reluctant sellers at present prices, owing to short production. Quotations are Rs.19.0½. for fine pale medicinal quality; Rs.14.10½. for good seconds; and Rs.13.14½. for thirds, in cases, per bazar maund weight, f.o.b. for prompt delivery. Buyers generally are holding off.

Saltpetre, superior lower refraction quality, continues very scarce, and rates are dearer, *viz.*:— Rs. 8.8. to Rs. 8.9. for ordinary 5% refraction quality, prompt delivery; and white Furrackabad refined 5% refraction qualities are quoted Rs.9.0. to Rs. 10.0. per factory maund weight, loose, for near and early deliveries. Supplies are light.

Bone meal.—Owing to the inclemency of weather, supplies of raw bones have been very small, and demand has been limited. The prices remain steady at Rs.72.0. for New Zealand quality, Rs. 68.0. for steamed quality, and Rs.62.0 for unsteamed quality, guaranteed 4½% ammonia, and 52% tribasic phosphate of lime, per ton of 20 cwts., f.o.b., packed in new "A" twill bags, of 200lbs. each net. Bone dust is still quoted at Rs.52.0 for steamed and Rs.50.0. for unsteamed, guaranteed 3¼% ammonia and 40% tribasic phosphate of lime per ton, f.o.b. Offerings of all grades are very moderate.

The salt market closed easy. Local stocks held, in maund weights, were, ex Liverpool, 595,333; Hamburg, 123,202; Saliff, 118,709; Spanish, 116,592; Port Said, 61,826; and Bombay, 125,529. Quotations per maund were:—Liverpool, Rs.50.0. to Rs.56.0; Hamburg, Rs.52.0. to Rs.60.0.; Saliff, Rs.50.0 to Rs.68.0.; Spanish, Rs.53.0. to Rs.74.0.; Port Said, Rs.52.0. to Rs.73.0.; and Bombay, Rs.53.0. to Rs.54.0. The Government of India, in a resolution, state that the time has now arrived for a general reduction in the rates of carriage of salt by railways, and the Railway Board direct that on and after the 1st December next, the maximum and minimum rates for salt on railways administered by the State shall be the same as those prescribed for coal.

CHEMICALS IN SPAIN.—II.

IN his report of the district of Bilbao for 1906, Mr. Consul Maclean remarks that the population of Bilbao is approaching 100,000, the majority dependent on the mines or industries connected therewith. It has been foreseen that some day the mines will be worked out, but all ore exported has been subjected to a tax, a portion of the product of which has provided the necessary funds for improving the river, port, and harbour, with the view of making Bilbao an important commercial port for Spain. The work has been in progress for some years and still continues, the progress being slow but satisfactory. It has already become a port of call for vessels from the United Kingdom, North and West Europe, trading with Central and South America, and new quays in deep water for the better accommodation of such vessels are in course of construction.

Statistics concerning the importation of Portland cement are not obtainable, but as there was no work undertaken during 1906, in which the British product was utilised, it is probable that there was a smaller quantity imported than in 1905. A beginning having been made in the construction of new quays, there may be a demand for Portland cement during the next two years. New buildings are being constructed of ferro-concrete, most of the cement used being produced in Spain.

A French company, established at Sestao, on the River Nervion, utilise in the manufacture of their cement the slag of the Vizcaya Ironworks. Besides the work they have undertaken in Bilbao and district, this company have obtained important construction contracts in other parts of Spain.

About 7,200 tons of tar were produced locally, principally by the Altos Hornos Ironworks. Of the products, some 1,667 tons of creosote were exported to France, Algeria, and Belgium, and 34 tons of carbolic acid to Germany; the remainder of the production was consumed in the country. Sulphate of ammonia is only produced by the ironworks; part is purchased locally for the manufacture of nitrate of ammonia, and the remainder is exported.

The Spanish olive oil crop showed a decrease of 12% compared with that of 1905, and this was reflected in shipments from Bilbao—5,727 gallons against 8,628.

Ordinary paints and varnishes are made in Spain, only the better qualities being imported from the United Kingdom. Soap is almost entirely manufactured locally, only a small quantity of toilet soap, chiefly from France, being imported. Perfumery is also imported from France.

The Unión Resinera Española produced during 1906—

——	Quantity.	Increase.
	Tons.	Tons.
Colophony	14,601	2,445
Turpentine	3,982	946

The sales in the country were:—Colophony 7,343 tons; turpentine 790 tons.

Some 2,490 tons of turpentine were sold abroad, principally to the North of Europe and Switzerland, whilst the United Kingdom took the major part of the 5,533 tons of colophony that were exported.

The fall in the rate of exchange has adversely affected this company's profits on sales abroad, but on the other hand, the cost of production has been reduced by improved methods. The company has invested 250,000 fr. in a society formed in Antwerp to control the French production, which is the principal competitor in Europe up to now of the Spanish company, and by this arrangement to regulate prices it expects to diminish speculation.

The following table shows principal imports into Bilbao during 1906:—

	U.K.	France.	Belgium.	Germany.	U.S.A.	Average for 5 years.
Bitumineous schists, petroleum.	449½	21½	393½	236½	3,888	4 714
Chrome ore	63½					152
Raw phosphates (since July only)					2,112	
Raw materials for chemical purposes (Netherlands)	163½	848	38½	16½	457	3,110½
Colours, dyes etc.	208¾	161¼	125½	63½	1½	5 74
Chemical and pharmaceutical products	4,171½	2,890½	6,628½	841½	5,765	18,786
Starch, stearine, soap, paraffin, wax, perfumery, explosives, and mining fuses.....	44½	6½	76½	181½	48	For 4 years only. 385½

Digitized by Google

SANTANDAR.

Mr. Vice-Consul Single reports that the port of Suances exported 12,968 tons of zinc ore, and those of Comillas, San Vicente de la Barquera and Tinamayor 4,650 tons. The greater portion of this ore was sent to Antwerp and Dunkirk.

The coal imported from the United Kingdom amounted to 86,442 tons, the greater portion of which was destined to the blast furnaces. The balance was taken by the railway and mining companies.

SWEDISH TRADE IN 1906.

MR. Consul M. Villiers, in his report on Swedish trade in 1906, states that British trade in Sweden might be much developed. Most of the Swedish exports go to the United Kingdom, but few of the imports come from there, the reason for this being that the traders do not know how to enter into trade with a country practically unrepresented by travellers.

Swedish matches continue to increase in popularity. The export for 1906 was 20,032 tons compared with 18,673 tons of the previous year.

Cement bids fair to become one of the principal articles of export; 38,548 tons were exported in 1905, and 45,959 tons in 1906. A considerable quantity was exported both to San Francisco and Valparaiso after the earthquakes, and is reported to have given satisfaction.

Chemical pulps have obtained good and steady prices; the export has increased; the returns to the manufacturers have been satisfactory; and, although the industry has been enormously expanded, both by enlargement of existing mills and the construction of many new ones in various directions, so that the possible production has been increased by 100,000 tons annually, the consumption has hitherto, at any rate, kept pace with the additional quantities produced. Mechanical pulp manufacturers, however, have not fared so well, as the price of timber rose about 20% in 1906 compared with 1905; but the price for pulp, though higher, has not risen in proportion. British imports have increased, but there is practically no increase in the production of mechanical pulps. The rise in prices of pulpwood is, moreover, expected to continue, owing to the requirements of the new sulphite mills.

The greatest rival of chemical pulp in the market is the esparto grass of Tunis. Steps are being contemplated to protect the growth of this grass, and, if a reduction of the crop results, Sweden hopes to benefit thereby. During the year 1906, of all wood pulp imported into the United Kingdom, 44% came from Sweden (35% in 1901); 38.1% from Norway (43.6% in 1901); and 7.4% from Canada (12.9% in 1901).

The discovery of a method of manufacturing artificial "india-rubber" opens out large possibilities. Samples were sent to the Board of Trade. Some large orders have been received from the United Kingdom. It can be very practically used for filling tyres; the trials have given great satisfaction.

The question of secret commissions, which has recently attracted legislative attention in the United Kingdom, has to be borne in mind in trading with Sweden, to judge from what is written in the Press, apart from what may be learnt from other quarters. The system of commissions, special discounts, and kindred methods seems to pervade transactions of all kinds and classes, from the purchases by domestic servants on behalf of their mistresses, to contracts of the largest and most important kind.

LULEA.

Mr. Vice-Consul Westerberg reports as follows:—The quantity of iron ore shipped from here during 1906 was 1,216,780 tons, showing an increase compared with 1905 of 144,780 tons. Of the total quantity shipped, 179,000 tons were intended for the United Kingdom, whereas 430,000 tons went to the Netherlands, 558,780 tons to north-west Germany, 21,700 tons to Belgium, and 26,400 tons to France. From the Kiruna and Tuolluvara mines 1,558,635 tons of iron ore were carried on the railway Kiruna-Norwegian frontier into Norway, whence the ore is shipped from.

NORRKOPING.

Mr. Vice-Consul Helander reports as follows:—Iron ore is exported in large quantities from Grangesberg viâ Oxelösund, from Gellivare viâ Luleä, and from Luossavaara and Kirunavaara by rail viâ Narvik in Norway, the whole business being nominally controlled by the Trafikaktieboleget Grängesberg-Oxelösund. The annual quantity to be exported from Luossavaara and Kirunavaara has been fixed by the Government at 1,200,000 tons, and on asking to be allowed to export an extra quantity of 400,000 tons in 1906, the company only got permission to export 300,000 tons, so the remainder of 100,000 tons had to be shipped viâ Oxelösund.

The export of iron ore from Oxelösund in 1906 amounted to the considerable figure of 786,663 tons, out of which 673,573 tons were carried to Rotterdam to be forwarded up the Rhine into Germany, 86,710 tons to Stettin, 19,525 tons to Emden, 2,180 tons to Middlesbrough, 2,040 tons to Antwerp, 1,430 tons to Lübeck, 769 tons to Finland, 238 tons to Hull, and 195 tons to Rendsburg.

HINTS TO SOAP EXPORTERS.

OPPORTUNITIES for export trade are better for toilet than for ordinary soaps, as the production of the latter abroad is greatly on the increase. The Far Eastern markets in particular offer openings for the sale of cheap toilet soaps; Japan and South Africa for the better kinds, whilst South and Central America purchase, principally, from abroad only the finer descriptions.

In the opinion of the Austro-Hungarian Consul at St. Gall, more business might be done in Switzerland in toilet soaps, with the aid of effective advertising and energetic travellers.

From Braila it is reported that perfumery is selling in Roumania in increasing quantities,as well as fine soaps, hair washes, and other articles of toilet.

A useful hint from Scutari is that toilet soaps should be strongly scented with musk in order to obtain a ready sale.

The needs of the Salonica market for toilet articles are of importance, as the purchases for the whole of the province are made there. British manufacturers have to meet active competition from French, Italian and German firms, and should take care to pay regular visits to this market in order to keep an eye on such foreign competition, and on the taste and requirements of buyers. If this is done, together with proper advertising, a considerable extension of trade in toilet soaps, perfumery, powders, tooth and hair-washes, as well as cosmetics, should eventuate. Salonica buyers are quite alive to the superiority of imported soaps over those of home manufacture. A form in which French soap sells well is in rectangular cakes of one kilo. at four silver piastres (8¾d.) a cake; the fact of its being sold by the manufacturer in a dry state finds favour. The Turkish soap, which is strong in caustic soda, retails at 4 piastres per ocque (78 ocque = 100 kg.) for white kinds, and at 3 to 3½ piastres for green sorts.

A French Consular report has been calling attention to the excellent chance of increasing business in Cyprus in perfumery and soaps. Common household soap is supplied chiefly by Turkey and Greece.

In Indian importations of soap a 50% increase, compared with the preceding year, took place in 1905. The greater consumption here indicated is contributed to by the poorer classes of Indians, who are likely to cause a still larger increase in importations in the future.

Soap is an important article of trade in Siam, and has increased considerably in demand in the last year or two. In the finer kinds, however, sales are still small. The most saleable descriptions are:—Cheap curd soap, in boxes of 50 and 100 lbs., in long bars; very cheap kinds of toilet soaps; also Windsor soaps in boxes of 50 to 100 tablets.

China, according to the Austro-Hungarian Consul at Hong-Kong, is showing a preference for almond scented yellow soap. The price for ordinary blue mottled soap at Hong-Kong is 12s. per 100 lbs., c.i.f.

In Abyssinia the trade is chiefly in the cheapest kinds of soap. It is sold in ½lb. bars, and costs at Djibouti about 40s. per 100 kilos. At Adis Abeba the price is somewhat higher.

Imports of soap and perfumery into Brazil are confined to the finest qualities, as medium and common kinds are made in the country. The first-named have to pay the same import duty as the medium quality goods, namely 4,000 reis per kg. gross, including packing, etc. Ordinary soap pays only 400 reis per kg., but the Brazilian Customs officials class practically all foreign soap as perfumed, and charge the higher rate.—*Handels Museum.*

THE SPANISH SUGAR BILL.—The Senate has passed the Bill or the regulation of the sugar industry by the prevention of ver-production.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements Relating to Continuous Electrolysis. G. B. Rambaldini, Milan, Italy. British Patent, 8,039, 1906. (Date claimed under International Convention, April 3, 1905.)

The inventor claims :—(1.) An electrolytic process dispensing with the use of porous walls and applicable to liquids, the decomposition of which gives rise to products one of which is soluble, the other solid or gaseous, said process being characterised by the fact that the electrolyte is regenerated by adding in a liquid form such amount of electrolyte as corresponds to the transport of the solid or gaseous ion freed, and to the solvent decomposed by secondary action, an equivalent quantity of liquid being allowed to flow out, and a quantity of electrolyte in anhydrous form being introduced at the electrode at which the solid or gaseous product is developed, as corresponds to the transport of the ion passing into the produced liquid. (2.) An electrolytic process as in Claim 1 characterised by the fact that in order to supply the said anhydrous salt, as well as the liquid electrolyte, the liquid in contact with the electrodes of the solid or gaseous product is caused to enter and leave the bath in a horizontal direction, the same liquid being caused continuously to circulate in series with an external reservoir to which the quantity of anhydrous salt and electrolytic liquid necessary to keep constant both the volume and the density, is being supplied, all the useful products generated at both of the electrodes being collected at the same time.

Improvements in or Relating to Ore Concentration and Apparatus Therefor. H. L. Sulman, 44 London Wall, London, and E. A. Sulman, South Grove, Highgate, London. British Patent, 9,981. April 28, 1906.

This invention relates to improvements in ore concentration and apparatus therefor, the object being to provide suitable means for separating metalliferous particles from gangue or from one another. The invention is an improvement upon that described in British Patent No. 5,620 of 1905.

The inventor observes that hitherto it has been proposed to separate mineral particles which are immersed in liquid by causing the particles to be exposed to the air and thereafter to meet the edge or surface of the liquid, whereby certain particles float and are separated from the remainder. In the methods previously proposed, powdered ore was carried on some form of moving surface such as a vanning apparatus or conveyor. According to this invention the powdered ore or mixed particles are fed over a surface over which a thin layer of liquid passes, and relatively movable members, such as squeegees, sweep over the surface, and cause the ore to be alternately exposed to the air and to the edge of the liquid. Preferably the powdered ore or mixed particles are fed over a fixed surface over which a thin layer of liquid passes, and the particles are mechanically caused to be alternately exposed to the air and to the edge of the layer of liquid, whereby certain particles float in the liquid and are separated from the remainder.

One apparatus for carrying out the invention comprises a fixed and preferably inclined surface, over which powdered ore and a thin layer of liquid are fed, and means for alternately exposing the ore to the air and to the edge of the liquid. Such means may consist of one or more movable members which sweep over the surface and temporarily remove the liquid from the ore particles. These movable members conveniently have a flexible edge in contact with the surface. The inclination of the surface should be such that the powdered ore will not flow off it of its own accord with the liquid when the mechanism is at rest, and the layer of liquid should be so thin that when the movable body or flexible edge passes over the ore it will remove the film of liquid and leave the ore particles exposed to the air for an appreciable time. The inclination is to be adjustable to meet the requirements of varying ores.

Improvements in Apparatus for Mixing, Attemperating, Condensing, or Effecting Reactions between Liquids and/or Gases. O. Guttmann, 12, Mark Lane, London. British Patent, 4,407. February 22, 1907.

The improved bodies or units, which are made of suitable material and of suitable size, are channel-like structures Λ- or ∩-shaped in cross section, and are provided with shoulders on their outer surface whereon another row of channels when superposed thereon rests. Perforations or slots near the shoulders are formed through the walls of the channels for the passage of the gases or liquids, so that when two or more units are superposed the one upon the other and so on, the whole forms a honeycombed or cellular structure, having intercommunicating reaction spaces formed between the successive layers or superposed units. Instead of making the channels single of a Λ- or ∩-shape with shoulders, they can be made of a W-shape or double channel, and any of the channels can also be used in a reversed position; instead of being made continuous channels from one end to the other, they can be divided in the length into compartments by inserting division walls at suitable intervals apart, and the inner and outer surfaces can be fluted or corrugated so as to increase the area of the contact surfaces.

SANTA CATALINA NITRATE CO.—The directors have declared a first quarterly dividend of 5% on account of the profits for the current year.

Molybdenite, Ltd.—Capital £5,000., in £1. shares. This company has been formed to acquire, deal with, and turn to account options, lands, buildings, mines, mining rights and leases, concessions, licenses, patents, etc. No initial public issue. Table A mainly applies. Registered by Harston and Bennett, 4, Bishopsgate Within, E.C.

Improved Smokeless Coal Co., Ltd.—Capital £5,100., in £1. shares. This company has been formed to carry on the business of colliery proprietors, coal merchants, coke manufacturers, smelters, etc. No initial public issue. The first directors are to be appointed by the subscribers. Qualification, £50. Registered office, 18, Fleet-street, E.C.

United Alkali Co., Ltd.—The directors have declared an interim dividend at the rate of 7% per annum on the preference shares, but have decided to defer the recommendation of a dividend on the ordinary shares until the end of the financial year.

Wills.—The will of the late Alderman James Liebig Muspratt, of Cornish, Flint, formerly of the firm of Muspratt Brothers, chemical manufacturers, Flint, J.P. for Flintshire (sheriff 1897) chairman of the Flintshire Education Committee, Alderman and ex-chairman of the Flintshire County Council, four times Mayor of Flint, and eldest son of Mr. Richard Muspratt, of Trelawny House, Flintshire, has been proved at £25,711.

ARTIFICIAL MANURE IN EGYPT.

SOME information regarding the growing importance of Egypt as a market for artificial manures is given in a recent French Consular report. Since the construction of the Assouan Dam, Egypt's most effective fertiliser, the mud of the River Nile, is becoming less sufficient for the needs of cultivation, as a large part of the mud is left far south of the Nile delta. Further, the area under cultivation has been considerably increased in extent, and through the help of irrigation works, consequently, the supply of cattle manure is quite inadequate to cover the whole ground. On cotton fields, good results have been obtained with 100 to 150 kilogs. of superphosphate per feddan (1.04 acre), often with 50 kilogs. nitrate of soda or sulphate of ammonia. On grain fields, 100 kilogs. nitrate with 40-50 superphosphate is the customary allowance per feddan. The following quotations for the most important fertilisers can only be considered approximate, as frequent variations take place. They amount per ton, free on waggon Alexandria, as follows: sulphate of ammonia, £13. 10s.; nitrate of soda, £12. 10s.; superphosphate, £3. 2s. The "Société Khédiviale d' Agriculture" sells to the farmers appropriate mixtures at the following rates per feddan: for cotton, £3. 9s. 6d.; maize, £1. 11s.; wheat, £1. 3s.

Price's Patent Candle Company.—Without making any deduction for depreciation the accounts for the half-year ended June 30 show a profit of about £29,800., to which has to be added £8,510. brought forward from last year. The directors recommend a dividend of 15s. per share, which will absorb £28,125., and leave about £10,200. to be carried forward.

Trade Notes.

The Radoch Chemical Co., of Sossnowies, made a profit of £8,280. in 1906, against a loss of £1,901. in the preceding year. The dividend will be 6%.

Woolcombers Limited.—The directors have decided to declare an interim dividend on the preference shares for the half-year ended June 30, at the rate of 7% per annum. Dividend warrants will be posted on August 19.

Fertilisers in Northern Spain.—A French Consular report calls attention to the demand for artificial fertilisers in the northern Spanish provinces of Galicia and Asturias. Generally speaking, the ground in Galicia is poor in phosphates; in consequence of this, other artificial manure containing the latter is much in request. As the land is also deficient in lime, the Thomas phosphates have given excellent results. The favourable action of almost any artificial fertiliser in Galicia and Asturias is increased by the frequent rain bursts, which hasten the solubility of these articles.

River Plate Vanadium Syndicate, Ltd.—Capital £20,000., in £1. shares. This syndicate has been formed to acquire the mines or mining concessions of vanadium ore and other minerals known as Venus and Bienvenida, near Soto, Province of Cordoba, Argentine, to adopt an agreement with J. E. Bonnemaison, and to carry on the business of miners, explorers, prospectors, metallurgists, dealers in ores, metals, and minerals, etc. No initial public issue. The first directors are A. E. Kempf, G. Kempf, W. R. Bowen, and J. E. Bonnemaison. Qualification, £100. Remuneration, £50. each per annum (chairman £100.) and 2½% of the distributed profits after 10% dividend has been paid, divided (maximum in any year, £3,000.). Registered office, 5, Fenchurch-street, E.C.

White Lead.—The *Manchester Guardian* says:—"The scarcity of white lead consequent upon a very unusual demand this year is beginning to cause some uneasiness. Prices have been comparatively high for a long time, but it seems likely that the trade has not yet witnessed the end of the upward movement. A position such as the present is extremely inconvenient to consumers, because while many things can be safely bought "from hand to mouth" white lead is not one of them. New carbonate of lead does not work well, and no painter who has a reputation to sustain cares to use it. On the other hand, to stock white lead with a view of using it a year hence, after it has matured, is disagreeable when the price reaches £27. or £28. per ton. The margin for a fall is tremendous, seeing that £14. or £15. per ton was a common figure a few years ago. The position of the makers is now very strong, and they are refusing orders on all hands; but at the same time the profits of the industry are by no means satisfactory, for, notwithstanding the scarcity, the price has not risen yet in proportion to the rise in the pig lead."

Market Reports.

THE AMERICAN CHEMICAL MARKET.

(Rate of Exchange, $4.85½ = £1.)

NEW YORK, July 16, 1907.

Nitrate of soda is steady at $2.45 to $2.50. per 100 lbs. as to position. Sulphate of ammonia is unchanged at $3.05. to $3.10. per 100 lbs. Grey muriate is in usual demand at 6c. to 6¼c. per lb. Lump sal ammoniac, good white seconds, 9¼c. per lb. Lump carbonate ammonia is without new feature at 7⅞c. to 8c. per lb. with powdered 1c. per lb. more. Bleaching powders are slow of sale at $1.30 to $1.35. Alkali is 92½c. per 100 lbs., for light 58%, in bags, f.o.r. makers' works. Caustic soda, 74%, is quoted at $2.05. per 100 lbs., same conditions. Sulphate of copper has been reduced by the Syndicate to 7c. per lb., in round lots. White powdered arsenic is lower for immediate delivery, at 7c. per lb., and it is now offered at the same price for the future. Red Saxony arsenic is firm at 7¼c. per lb. Calcined carbonate potash, 80-85%, is 7¾c. to 8c. per lb., and hydrated is steady at 7⅞c. per lb. Caustic potash, 75%, is steady at 4¼c.. per lb. Prussiate of soda is 9½c. to 10c. per lb., and potash 15¾c. to 16c. Bichromate of soda is 7⅛c., and potash 8¼c. per lb., the Syndicate prices. Phosphate of soda is dull at $1.85. per 100 lbs. Oxalic acid is well maintained at 8¼c. to 9c. per lb.

TAR AND AMMONIA PRODUCTS.

Friday.

Benzols quiet, with values given at 8¼d. to 8½d. for 90's, and 9d. for 50-90's. Crude tar, 15s. 6d. to 21s. per ton, Thames; 1⅛d. to 1⅜d. per gallon, delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d.; pitch (London) 26s. to 26s. 6d., f.o.b.; Gas Company, 29s. to 30s.; East Coast, 25s. to 25s. 6d.; West Coast, 24s. to 24s. 6d.; next year, 2s. more. Naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 11½d.; pure, 1s. 6d. to 1s. 7d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5⅝d.; 60%, 1s. 7½d. to 1s. 8d.; 75%, 1s. 11¾d. to 2s. Crystals, 39-40, 5⅜d.; 34-35, 5⅜d. Cresylic, 95%, 1s. 1½d. to 1s. 2d. Anthracene, 40 to 45 per cent. A, 1¼d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quiet. Nearest values are:—Beckton, £12. 2s. 6d.; Beckton terms, £11. 13s. 9d.; London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s. to £11. 16s. 3d.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d.; Liverpool, ordinary, 11s., and refined, 11s. 3d. Official quotations:—Cargoes, off coast or due, 11s. 3d.; ditto, for prompt shipment, 11s. 6½d.

FERTILISER MATERIALS.

Friday.

The market for all descriptions of manure material remains quiet, though prices are well maintained.

Nitrate of soda is a shade dearer on spot, closing quotations being 11s. 1½d. per cwt. for 95%, and 11s. 4½d. per cwt. for refined quality.

Shippers of East Indian bone meal, 42 and 52% quality, are still firm, at £5. 2s. 6d. per ton, net, c.i.f. Liverpool. On spot, £5. 7s. 6d. to £5. 12s. 6d. per ton, ex store, is required, according to quality.

Mineral phosphates of all grades remain unchanged.

THE LONDON METAL MARKETS.

Thursday.

Copper: Standard brands, £86. 15s. to £87. 5s. cash, and £83. to £83. 5s. three months. Tin: G.M. quality, £182. 10s. to £183. cash, and £181. 5s. to £181. 15s. three months. English, £184. Lead: soft foreign, £19. 15s. on spot, and August delivery, £19. 15s.; September, £19. 10s.; English, £20. 5s. to £20. 10s. Spelter: ordinary brands, £23. 2s. 6d., ex ship; hard, £19. 5s. to £19 10s., f.o.b. Antimony, £43. to £47.; ore, £10. to £10. 10s. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 16s. Nickel: £175. to £185. Pig-iron: closing prices, standard, 56s. 6d. cash, and 56s. 7½d. one month; Cleveland, 57s. 5d. cash, and 57s. 1½d. one month.

MISCELLANEOUS CHEMICAL MARKET.

Friday.

There is a continued steady demand for chemicals generally, and with the high prices ruling for all raw materials there is no tendency to any reduction of prices in manufactured products. In the alkali trade demand continues good for alkali, 58%, quotation being firm at £4 10s., bags, f.o.r.; and for soda crystals, in bags, 60s. per ton, f.o.r. Caustic soda also stands very firm, at £9. 15s., f.o.b. Liverpool. Saltcake is in good request, both for prompt and forward delivery, at 40s. per ton, in bulk, f.o.r. Potash, caustic and carbonate, are still in strong demand, and supplies are not abundant. Caustic potash, 88/90%, is firm, at £26. per ton. Sulphur is steady, at £4. 17s. 6d., and there is good general demand for sulphuric and muriatic acids. Sulphate of copper is rather easier, at £30. 5s., f.o.b. Arsenic firm and in good request, at £32. Acetate of lime, grey, 80%, is still at £12 10s., and there is continued good demand for acetic acid and other acids. Bichromates are unchanged. Prussiates also are steady, at 3¾d. and 6d. per lb. For ammonia and ammonia salts the demand is well sustained, and prices are firm.

LIVERPOOL DRYSALTERIES.

Thursday

Montreal potashes quiet. Pearl ash quotations nominal. Bark steady, with only small supplies of Baltimore. Berries unchanged. Logwood and fustic steady. Cutch very quiet. Gum arabic steady. Castor oil quiet, at 3½d. for good seconds Calcutta; 3⅝d. to 3¾d. for first pressure French; and 3½d. for econd pressure French; Calcutta well held at 3¾d. per lb. for July-August shipment. Gambier quiet at 18s per cwt.; cubes 28s. to 28s. 6d. on spot; 27s. 6d. for July-August shipment, and 27s. 9d. for August-September shipment. Shellac quiet, with sales of T.N. orange on spot at 206s. to 207s. American powdered starch 10s. on spot, and 9s. 6d. c.i.f. for shipment. Pearl: on spot, 9s. 4½d. and 9s. c.i.f. for shipment. Cream of tartar, 98%, foreign powder, 81s.; 95%, 79s. Tartaric acid, English, on spot, 11¼d.; foreign, 11d. Citric acid, English, 1s. 11½d.; foreign, 1s. 11¼d.

LIVERPOOL OIL AND COLOUR MARKET.

Thursday.

OILS.—Palm oil steady, sales including Grand Bassa and Dix Cove on spot at £28. 2s. 6d; Olive oil firm. Linseed oil quiet, at 25s. 9d. to 26s. 6d. for Liverpool makes in export casks. Cottonseed oil steady at 31s. 6d. to 32s. per cwt. for Liverpool refined, in export barrels. Rosin, on spot, 11s. 10½d. for common. Tallow quiet at 35s. per cwt., c.i.f, South American mutton. Turpentine quiet at 42s. 6d. per cwt. Petroleum: Russian and Roumanian, 6¼d.; and American refined at 6⅞d. to 7⅛d. per gallon. Petroleum spirit steady at 1s. 0½d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

TYNE CHEMICAL REPORT.

Thursday.

Chemicals steady and in fair demand. Caustic soda, 76-77%, £10. 10s.; and 70%, £9. 15s. per ton. Bleaching powder in better request at £5. to £5. 5s. per ton. Soda crystals, locally firm, £2. 17s. 6d. to £3. 2s. 6d. per ton gross weights. Sulphur firm at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett, do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market very firm with a full demand, and all qualities of coal in strong request. To-day's prices:—Best Northumbrian steam, 15s. 9d. to 16s. per ton; second qualities, 14s. 6d. to 15s. 3d. per ton; small steam coals, 10s. to 10s. 6d. per ton; best gas coals, 12s. 6d. to 15s. per ton; Durham bunker coals, 12s. 9d. to 13s. 6d. per ton; coking coals, 13s. 6d. per ton; household coals, 15s to 17s. per ton; foundry coke, 24s. to 25. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Thursday.

The market in the section of the Scotch makes of paraffins (solid and liquid) and mineral oils continues very steady, with a fair and regular turn-over at prices as for some time ruling. Within the next week or two the managing representatives of the various companies will meet in Glasgow to come to some understanding (the usual annual custom) with regard to the contract prices of burning oil for the approaching new season, 1907-1908. The article is firm, and an advance on present spot price figures is not unlikely. The general chemicals market shows little of change, the heavy lines with values as before, but the demand a little brisker. Sulphate of ammonia remains as

Digitized by Google

before, £12. to £12. 1s. 3d. for spot f.o.b. Leith, and with only a moderate inquiry. Sulphate of copper is again fractionally easier.

Chief prices current are :—Alum (in lump) £5. 5s. to £6. nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d. ; and 1-cwt. casks, £6. 15s. nett, Liverpool ; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b., Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b., Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne ; borax, English refined, £16. ; and boracic acid, £25., nett, Glasgow ; caustic soda, white, 76°, £10. 10s. ; 70-72°, £9. 15s. ; 60-62°, £8. 15s. ; and cream, 60-62°, £8. 15s., all nett, Liverpool ; chlorate of potash, 3½d., nett, Glasgow ; creosote (ordinary coal-tar and blast-furnace) 2¼d., naked, f.a.s., Glasgow ; nitrate of soda, 11s. 3d. ; paraffin scale, hard, 2d. to 2¼d. ; and soft, 2⅜d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d. ; paraffin spirit (naphtha), 10d. to 11d. per gallon ; paraffin oil (burning), special quality, 6½d. ; ordinary sorts, 6d. and 5¾d., open market prices for spot business at Glasgow and other big centres ; ditto (lubricating) 865°, £5. 12s. 6d. to £5. 17s. 6d. ; 885°, £6. 7s. 6d. to £7. 7s. 6d. ; and 890-895°, £7. 2s. 6d. to £8. 2s. 6d. ; prussiate of potash, 6d., nett, f.a.s. Glasgow ; salammoniac, first and second white, £42. and £40., less 2½% any port ; saltcake, 40s. to £42s. 6d. ; soda ash, £5. 10s. to £5. 15s. nett Tyne ; soda crystals, £3. to £3. 2s. 6d. ; sulphate of ammonia, £12. to £12. 1s. 3d. prompt, f.o.b. Leith ; sulphate of copper, £30. 10s., less 5% Liverpool, prompt.

New Companies.

Aristodes Dustless Roads Syndicate, Ltd.—Capital £2,000., in £1. shares. This syndicate has been formed to adopt an agreement with J. W. Metcalf, to acquire the patents granted to him for an invention for a new method of tarring roads and apparatus and machinery therefor, together with any subsequent inventions therein, and to develop and turn to account the same. No initial public issue. The first directors are J. W. Metcalf, A. Stedall, W. C. Manning and A. S. Manning. Registered office, Rutland Chambers, Newmarket.

Cumberland Mines, Ltd.—Capital £40,000., in £1. shares. This company has been formed to adopt an agreement with T. C. Dennison, J. F. Lobb and F. Meakin, to acquire any mines, mining rights or metalliferous land in the United Kingdom or elsewhere, and to carry on the business of miners, prospectors, explorers, dealers in metals and mineral substances, etc. No initial public issue. The first directors are T. C. Dennison, J. F. Lobb, R. C. Skeet and F. Meakin ; qualification (except first directors) £500. Registered office, 6, Martin's-lane, Cannon-street, E.C.

J. H. Riddle, Ltd.—Capital £6,000., in £10. shares. This company has been formed to take over the business of soap manufacturers carried on by J. H. Riddle and J. Unsworth, at Newton Soap Works, Manchester, as J. H. Riddle. No initial public issue. The managing directors are J. H. Riddle and J. Unsworth (both permanent) ; qualification £250. ; remuneration of managing directors £250. each per annum. Registered office, Newton Soap Works, Holland-street, Manchester.

Monazite, Ltd.—Capital £7,500., in £1. shares. This company has been formed to carry on the business of company promoters, financiers, etc. No initial public issue. The subscribers are to appoint the first directors ; qualification £10. Registered by H. A. Phillips, 16, South-street, Finsbury, E.C.

National Explosives Co. (1907) Ltd.—Capital £500., in 10s. shares. This company has been formed to adopt an agreement with the National Explosives Co., Ltd., and to carry on the business of manufacturers of and dealers in explosives of all kinds, etc. Minimum cash subscription 7 shares. Table A mainly applies. The directors may increase the capital to not more than £133,500. in 134,000 preference shares and 133,000 ordinary shares of 10s. each, and may borrow up to £200,000., of which £150,000. may be by the issue of debenture or debenture stock. Registered by Paines, Blyth and Huxtable, 14, St. Helen's place, E.C.

United Serdang (Sumatra) Rubber Plantations, Ltd.—Capital £170,000., in £1. shares. This company has been formed to acquire estates on the East Coast of Sumatra and elsewhere, to adopt agreements (1) with the partners in the firm of Harrison and Crossfield for the sale and purchase of the Bergerpang Estate, Serdang, (2) with Paul L. J. Francis Count de Guigne, C. J. de Guigne and G. C. A. de Guigne, and (3) with H. W. Brett, and to carry on the business of growers of rubber, cocoa-nuts and other produce, etc. The first directors (not less than 4 nor more than 8) are A. Lampard, C. E. Morrison, F. E. Savill, H. W. Brett, K. F. Arbuthnot and A. M. E. de Guigne ; qualification £500. ; remuneration £100. per annum. Registered by Warren, Murton and Miller, 45, Bloomsbury-square, W.C.

Sungei Jong Rubber Co. Ltd.—Capital £7,000., in £10. shares. This company has been formed to acquire certain lands and properties at Sungei Jong, near Chenderiang, State of Perak, and to carry on the business of growers and manufacturers of and dealers in indiarubber and other produce, etc. No initial public issue. M. Duncan is the first director. Registered by T. T. Hull and Son, 22, Chancery-lane, W.C.

National Match Factory of Bolivia, Ltd.—Capital £80,000., in £1. shares (30,000 preference). This company has been formed to carry on the business of match manufacturers, importers, exporters, and salesmen, timber growers and merchants, sawmill proprietors, etc., in Bolivia or elsewhere. No initial public issue. The first directors are to be appointed by the subscribers ; qualification 2 shares ; remuneration (except managing director) £150. each per annum and 10% of any distributed profits remaining after paying 10% on the ordinary shares. Registered by Francis Vowles and Welch, 84, Bishopsgate-street Within, E.C.

Oued-Mongras Copper and Iron Co., Ltd.—Capital £30,000., in £1. shares. This company has been formed to carry out an agreement between James A. French, liquidator of the Oued-Mougras Copper and Iron Co., Ltd. (in liquidation), John A. Nicol, Coatbridge, and Charles S. Mair, merchant, Tigh-na-Mara, Algeria ; to prospect and explore the property referred to therein in the province of Constantine, Algeria, and to carry on in Africa or elsewhere the business of copper, iron and general miners, prospectors, explorers, etc. The first directors are C. S. Mair, T. Hunter, T. Stewart, D. B. Allan, and J. Alston ; qualification 500 shares ; remuneration £50. each per annum. Registered office, 135, Wellington-street, Glasgow.

LATE ADVERTISEMENTS.

CHEMIST, experienced in oil and paint analysis and works management, also in analysis of all kinds of tannin and dyewood materials and drysalteries, desires Situation; young and energetic; best references. —"1,462," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

TECHNICAL Chemist, at present engaged, but desiring a change, is open to negotiate with firm requiring first-class man as Works Manager. Advertiser, who has filled responsible and important positions, is well up in pure and applied chemistry and in chemical engineering, having had an exceptionally wide and varied manufacturing and commercial experience in connection with chemical trade; would be specially useful to any firm seeking to extend their manufacturing operations. Communications to be strictly confidential.—Reply, Box "1,459," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

WANTED experienced Distiller for stearine and fatty acids, with experience of vacuum plants.—Apply, "1,463," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

CHEMISTRY Associate of the Royal College of Science, aged 22, one year organic research, desires Post in works or laboratory.—Address, 4, Lothian Road, Grove Hill, Middlesbrough

BORRIES CRAIG & CO., Newcastle-on-Tyne, Appointed Sellers of Oxalic Acid, Sal Acetos, Neutral Oxalate, Oxalate of Ammonia, of Pritchard's well-known make Inquiries will be esteemed.

Notices.

All communications for the *Chemical Trade Journal* should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**

Half-Yearly (26 numbers) ..... **6s. 6d.**

Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Readers will oblige by making their remittances or subscriptions by Postal or Post Office Order, crossed and payable to "Davis Bros."

THE BRITISH ASSOCIATION.

SECTIONAL PROCEEDINGS.

SECTION B.—CHEMISTRY.

IN his address to the Chemical Section, the President, Professor A. Smithells, B.Sc., F.R.S., said :—

The year which has elapsed since the meeting of our Section at York has been eventful in the most melancholy of ways; the losses sustained by our science have been unparalleled. The passing bell seems to have tolled almost without intermission as one after another of our masters has been taken from us: in Russia, Mendeléef, Menschutkin, and Beilstein; in France, Berthelot and Moissan; in Holland, Bakhuis-Roozeboom. Whilst in some of these cases we may find consolation in contemplating a length of life and sustained activity beyond what we might have dared to expect, in others our regret is increased by the sense of untimeliness and of vanished hopes. I am tempted to speak of the work of such mighty men as Berthelot and Mendeléef, to dwell upon the discoveries by which they transformed the whole fabric of chemical science; but this is not the occasion on which to offer an estimate of the labours of those who have passed away. I can only say that in the bond of brotherhood which the pursuit of science establishes among the different nations of the earth we who are Englishmen feel and deplore these losses as our own. I must not omit to allude also, as I do with deep regret, to the death in our own country of two such ardent and fruitful workers as Cornelius O'Sullivan and Robert Warington.

These words were already in print when again we were called to mourn the loss of one of our greatest men, one who but a year ago was the subject of our special rejoicings, and whose vigour of body and youthfulness of spirit seemed to promise the long continuance of a noble and an extraordinarily fruitful life. We can at least feel thankful that William Henry Perkin lived long enough to learn in what honour and esteem his name was held, not only among his countrymen, but by all the chemists of the world, and by the leaders of those great industries of which he was justly acclaimed the founder. For more than a generation Sir William Perkin had been one of the most familiar figures at the meetings of this Section, and greatly shall we miss his gentle presence, his wise counsel, and his valued contributions.

THE CHEMISTRY OF FLAME.

I can, perhaps, best occupy your time to-day by attempting to give some account of the present state of the scientific subject to which I have paid most attention. The topic of flame, after a long period of repose, has aroused much interest during late years, and I think we may say that some considerable progress has been made in its elucidation, although in this, as in all other subjects of

Digitized by Google

scientific inquiry, the more closely we scrutinise it the more impressed must we be with what still remains unknown.

One of the first questions that meet us in the study of flame is that of the temperature at which in any given case the phenomenon becomes evident. Here, I think, a great clarification of view has taken place. The old idea that there existed a fixed temperature at which inflammation suddenly took place cannot now be maintained, and the term "ignition temperature" has acquired a different meaning. It is now known that in a very great number of cases a mixture of two flame-forming gases, when gradually raised in temperature, will develop luminosity quite gradually, *pari passu*, with the chemical combination that is being induced. This phenomenon is, of course, known universally in connection with phosphorus, but it is not so widely known in connection with other combustible substances. There are some simple facts that seem as if they could never gain admission to text-books, and I do not think I have known more than a single chemical book that is not likely to leave a student under the impression that the phosphorescence of phosphorus is an almost unique phenomenon. I do not know how many times the independent discovery has been made that sulphur, arsenic, carbon disulphide, alcohol, ether, paraffin, and a whole host of other compounds, inorganic and organic, will phosphoresce as truly as phosphorus itself; that, in fact, phosphorescent combustion is the normal phenomenon antecedent to what we ordinarily call flame.

This is, after all, only in harmony with the general truth that chemical combination between two gases does not set in suddenly, but comes into evidence quite gradually as the temperature is raised from a point at which the action, if it occurs at all, is so slow as to be negligible. The increase in the rate of combination is, of course, very rapid as compared with the increase of temperature, a difference of about 10° C. serving to double it. The interval between the beginning of phosphorescence and the production of vigorous flames may therefore be very short. In the case of phosphorus this interval, being from 7° to 60° C., includes ordinary atmospheric temperatures; hence the phosphorescence of phosphorus is a phenomenon that could not well be overlooked. If the prevailing terrestrial temperature were below 7° C., at which, under normal air-pressure, the phosphorescence of phosphorus ceases, it is possible that this element might never have acquired its peculiar reputation; it would not have shone in the dark, and in lighting it with a taper the phosphorescent interval would have been passed over as quickly as is ordinarily the case in the ignition of sulphur, paraffin, and other common combustibles. To make phosphorescence apparent in these last cases it is necessary to take special care to heat up a mixture of the combustible gas and air gently, and to maintain it at a temperature approaching, but not quite reaching, that of ignition. There is no simpler way than that used by Sir William Perkin, who brought the combustible substance near to, or in contact with, a massive metal ball previously heated to the suitable temperature.

The change from phosphorescence to ordinary flame is not sudden, but the appearance of ordinary flame is the end point of a continuous, though rapid, development. This end point is the temperature of ignition. What, then, determines the temperature of ignition? The answer to this question has been given with characteristic conciseness by Van't Hoff as "the temperature at which the initial loss of heat due to conduction, etc., is equal to the heat evolved in the same time by the chemical reaction."

We may obtain a clear idea of the meaning of temperature of ignition by supposing a combustible mixture of gases such as that of air and the vapour of carbon disulphide to issue through an orifice into an indifferent atmosphere. If we surround the orifice by a ring of platinum wire, which is gradually heated up by a current of electricity, a flame will gradually make its appearance. If, as soon as this is observed, the heating of the wire by the current be discontinued, the flame will disappear; it is, in fact, not self supporting, but depends on the accessory supply of heat through the electrically heated wire. If now we raise the ring to a higher temperature we shall get a brighter flame, owing to an increased rate of chemical action, and at last we shall reach a point where it is possible to cut off the electric current without causing at the same time the extinction of the flame. This is the true temperature of ignition, the temperature at which the reaction proceeds at a rate just sufficient to overbalance the loss of heat by radiation, conduction, and convection from the burning layer of gases, so that the next layer is put in the same state, and steady combustion proceeds.

Phosphorescence has been spoken of as degraded combustion, and, though literally the appellation is correct, I think it is liable to be misunderstood. Again, it is often supposed that phosphorescence is necessarily associated with the formation of incompletely oxidised products. This may be the case in a chemical system which is capable of affording different products at different temperatures, but it is not an essential feature; the phosphorescent combustion of sulphur, for example, affords nothing but sulphur dioxide.

Temperature of ignition is, then, neither a temperature at which combination suddenly begins nor one dependent solely on the nature of the combining gases. It will vary with the proportion in which the gases are mixed and with their pressure and other circumstances. Notwithstanding the simplicity of this conception, it must be admitted that there are many obscure facts connected with the ignition of gases. The inflammability of gaseous mixtures is not necessarily greatest when they are mixed in the proportions theoretically required for complete combination; the influence of foreign gases does not appear to follow any simple law; the presence of a very small quantity of a foreign gas may exercise a profound influence on the ignition temperature, as in the case of the addition of ethylene to hydrogen. When a mixture of methane and air is raised to its ignition temperature, a sensible interval (about 10 seconds) elapses before inflammation occurs. These facts are cognate to others which have increased upon us so abundantly in connection with the influence of moisture on chemical change. The study of the oxidation of phosphorus in particular brings us among rocks and shoals. Apart from the influence of moisture on the combination, we have the limitation of the process by a certain tension of oxygen and by minute quantities of a vast number of chemical substances, among which, in spite of much labour, no other common bond can be found. We do not know what oxide is initially formed in the oxidation, and the existence of the oxides P_4O and P_2O is as confidently disputed as it is affirmed. There is some reason for believing that the phosphorescence connected with phosphorus succeeds the formation of one oxide and accompanies the formation of another. The state of the oxygen, whether atomic, ionic, or molecular, which acts on phosphorus, the induced oxidation of other substances, the ionisation of air accompanying the oxidation—these are all matters concerning which there exists a bewildering literature that hangs over us like a cloud. The whole of my address would, in fact, not suffice for a summary of the state of our ignorance about the oxidation of phosphorus. The subject, simple as it appears at first sight, is really involved with a vast number of unsolved chemical problems the elucidation of which would throw much light on chemical action in general. I may, perhaps, bequeath the topic to some successor to this chair as one which may serve to illustrate the advance of knowledge since these present days of darkness.

The structure of flames has always been regarded as dependent upon the chemical changes taking place in the differentiated regions, but until recent times little attention has been given to any question beyond the cause of the bright luminosity of hydrocarbon flames. In a flame such as that of hydrogen or carbon monoxide, where we have some reason to suppose that

Digitized by Google

the same kind of chemical transaction is taking place throughout the region of combustion, we should not expect to find a differentiation of structure, and, as a matter of fact, we do not find any. Erroneous ideas have gained currency from the use of impure gases, and hydrogen is still described as burning with a pale blue flame, although Stas long ago stated that if the gas is highly purified, and the air freed from dust, the flame even in a dark room can only be discovered by feeling for it; a fact consistent with the line spectrum of water lying wholly in the ultra-violet. The presence of a very small quantity of free oxygen in carbon monoxide destroys the perfect simplicity of the single shell of blue flame with which the purified gas burns, and in other flames small quantities of gaseous impurities or of atmospheric dust give rise to features of structure and halos which have been frequently supposed to pertain to the flame of the combining gases. The fringe of a flame in air may be often tinged by the presence of oxides of nitrogen.

No flame better illustrates the relation of structure to chemical processes than that of cyanogen, where the two steps in the oxidation of the carbon are clearly marked out in colour. Apart from hydrocarbon flames, very few others have been carefully explored from this point of view. There is, unfortunately, no gas composed of two combustible gaseous elements; and, though such gases as the hydrides of phosphorus and sulphur do not fall far short of this, the experimental difficulties of an exact exploration of their flames are very great. We are thus prevented from studying the flame of a composite combustible in its simplest form.

The flames of hydrocarbons have naturally been the subject of most frequent investigation. The use of single hydrocarbons instead of the mixtures present in coal-gas and other common combustibles has simplified the study considerably. Two problems stand out prominently: one is to trace the steps in the oxidation of the hydrocarbon, the other to account for the bright patch of yellow luminosity. With regard to the question of the luminosity, I do not think there is any longer doubt about its being due essentially to the separation within the flame of minute solid particles of what is practically carbon. The separation seems to be adequately explained by the high temperature of the blue burning walls of the flame, which decomposes the unburned hydrocarbon within. In a similar way arsenic and sulphur and phosphorus are liberated within flames of their hydrides; but these elements, being volatile, do not appear as solids unless a cold object be placed within the flame. In the case of the hydride of silicon the liberated element at once oxidises to form the solid non-volatile oxide, which gives a bright glow.

The mode in which a hydrocarbon yields carbon by the application of a high temperature has been the subject of experiment and of hypothesis; but neither the view of Berthelot, that the carbon results from a continuous coalescence of hydrocarbon molecules with elimination of hydrogen, nor that of Lewes, according to which the formation and sudden decomposition of acetylene is the essence of the phenomenon, appears to me to be in harmony with the experimental facts; and I am not aware that either view has secured any support from other workers in this field. It is certainly not easy to ascertain experimentally the changes undergone by a single hydrocarbon as its temperature is raised, and at the last it may be objected that the course of events in contact with the solid walls of a containing vessel is not necessarily the same as that within the gaseous envelope of a flame. I am glad to think that there is promise of further light on this subject from the work of Professor Bone.

The course of oxidation of hydrocarbons has been the subject of very careful and fruitful study. The old view that a selective or preferential oxidation of the hydrogen always took place, that with a restricted supply of oxygen the hydrogen was oxidised and the carbon set free, is, I think, no longer maintained by anyone who has studied the question. The explosion of ethylene with its own volume of oxygen, which leaves us with practically all the carbon oxidised and all the hydrogen free, is fatal to this view. Again, when hydrocarbons are burned in a flame with a restricted supply of air, as is the case in the inner cone of the flame of a well-aerated Bunsen burner, there is clearly no separation of solid carbon, and the products of combustion when withdrawn and analysed disclose the presence of much free hydrogen and no unoxidised carbon. In describing this experimental fact I have spoken of it as the preferential oxidation of carbon. I have always thought it pedantic to quarrel with that expression; for, in speaking of a chemical transaction, we usually include only a description of the initial and final states of combination. I should be sorry, however, to detach the expression from the facts it describes and to exalt it into a general doctrine. That would be quite inadmissible, and, if there is any danger of misunderstanding, it would be better to avoid using the expression.

The admirable researches carried out in the University of Manchester by Professor Bone and his collaborators have afforded most valuable information as to the oxidation of hydrocarbons at temperatures extending from those of incipient oxidation up to the highest ones that prevail in a flame. According to Professor Bone, the oxidation of a hydrocarbon involves nothing in the nature of a selective or preferential oxidation of the carbon or the hydrogen; but it occurs in several well-defined stages, during which oxygen enters into and is incorporated with the hydrocarbon molecule, forming oxygenated intermediate products, among which are alcohols and aldehydes. The reaction, just referred to, between ethylene and an equal volume of oxygen is, according to Professor Bone, to be represented by this scheme:

$$\begin{matrix} CH_2 \\ \vdots \\ CH_2 \end{matrix} \longrightarrow \begin{matrix} CH.OH \\ \vdots \\ CH_2 \end{matrix} \longrightarrow \begin{matrix} CH.OH \\ \vdots \\ CH.OH \end{matrix} \longrightarrow \begin{matrix} H_2C:O \\ | \\ H_2C:O \end{matrix} \longrightarrow \begin{matrix} H_2+CO \\ | \\ H_2+CO \end{matrix}$$

There can be no question about the facts on which this scheme is based, and they are a new and important addition to knowledge.

It is a great aid to the study of chemical changes, when we can resolve them into stages, whether or not these stages be realisable under certain experimental conditions. In this way we can get a clear view of the relationship between the action under one set of circumstances to the action under another set; and in this way also we can often establish rational links between reactions which at first sight seem quite disconnected. Intermediate reactions are much used to elucidate cases of contact action, and in the processes of organic chemistry they are almost universally assumed.

I am far from wishing to disparage these practices, but I think it important that we should realise how far we are dealing with convenient devices and how far with ascertained facts. The isolation of an intermediate product under one set of circumstances is in itself no proof that this product is transitorily formed when the reaction is proceeding under another set of circumstances; and if we were to assume generally that because we can represent a chemical transaction as if it were due to a successive construction and destruction of a series of molecular edifices it actually does take such a course, we should, I think, be making the same kind of mistake as to suppose that in the application of two differently directed forces to a body at rest, the body will move successively in the direction of each force instead of moving immediately in the direction of their resultant. I know that I may be considered hypercritical, and perhaps obstinate, in this matter; but I wished to state the reasons that prevent me from accepting entirely the interpretation which Professor Bone has given to his experimental results, and to draw attention to a question of general importance that has not, I think, received the attention it deserves.

The mode of burning of carbon, whether in the free state or as a constituent of a compound, is not at all easy to determine; and notwithstanding many investigations, among which must be specially mentioned those of Professor H. B. Dixon and his collaborators, so simple-looking a question as whether carbon forms carbon monoxide by directly uniting with oxygen, or only by reducing carbon dioxide, is still a matter of uncertainty.

Our knowledge concerning the question of flame temperatures has been much improved in recent times, thanks mainly to the admirable work of M. Le Chatelier. The well-known memoir of Mallard and Le Chatelier on the explosion of gases supplied the data which first permitted of a moderately exact calculation of flame temperatures, and the perfection of a thermo-couple by M. Le Chatelier gave us the first instrument that could be used directly for making a satisfactory measurement. The uncertainty connected with this subject may be well illustrated by quoting the temperatures that have at different times been ascribed to the flame of coal-gas when burnt in a Bunsen burner, where we have had values varying from 1,230° to 2,350° C.

The question of calculating the temperature attained during combustion by reference to calorimetric values, specific heat, dissociation, and other considerations is to form the subject of a joint discussion with Section G during the present meeting, so that I shall not here enlarge upon it.

With regard to the use of thermo-couples, I may remark that the practical difficulties have been successfully met. The chief difficulty is, of course, to secure that the thermo-junction attains as nearly as possible the temperature of the region in which it is immersed. As ordinary flames consist of thin shells of burning gases, on either side of which there is a very rapid fall

Digitized by Google

of temperature, it is necessary to use thin wires, and to dispose them so that there is no appreciable drain of heat from the junction. By using wires of different gauge for the couples it is possible by extrapolation to arrive at a temperature for a couple of infinitely small cross-section, and it is also possible to make a correction for the superior radiating power of the couple as compared with the flame-gases. Without this last correction a maximum temperature of 1,770° was obtained for the Bunsen flame by Waggener in Germany, and 1,780° by White and Traver in America. Correcting for radiation, Berkenbusch found 1,830° as the maximum temperature.

M. Féry, by an ingenious application of his beautiful optical pyrometer to a flame containing sodium, gives 1,871° as the highest temperature of the flame of a Bunsen burner burning coal-gas.

The consideration of flame temperatures has become of increasing importance in the arts, owing to the use of the Welsbach mantle as a means of deriving light from coal-gas. The great improvements which have been made in the efficiency of atmospheric burners depend primarily on the fact that the smaller the external surface we can give to a flame consuming gas at a fixed rate the higher must be the average temperature; and since the emission of light from a mantle is proportional to a high power of the absolute temperature, a small increase of temperature is of great effect on luminosity.

The acetylene-oxygen flame in which a temperature of about 3,500° prevails, not very different from that of the electric arc, is the hottest of the hydrocarbon flames, and finds some important practical uses.

I have already said something about the luminosity of flames so far as relates to the separation and glow of solid carbon. But there remains the more general question of the luminosity of flames containing nothing but gases. The older explanation of the emission of light from combining gases said no more than that the energy liberated during the reaction and appearing as heat raised the product to incandescence—that is to say, so increased the velocity of its molecules and the violence of their collisions that vibrations were set up whose wave-lengths lay within the limits of visible radiation. This explanation has long been questioned, and there is now, I think, a very general agreement that it will not suffice. The average temperature, in fact, prevailing in a flame, if attained in the product of combustion by the supply of heat from outside, does not suffice to make that substance luminous. We are therefore thrown back upon the conclusion that the generation of light in a flame is not a consequence, though it is an accompaniment, of the elevation of temperature. The question now is, Can we go any further? To do this we are led to consider individual molecular transactions instead of statistical averages, and the view presents itself that the combining atoms may, in losing their chemical energy, form directly systems of independent vibration where the radiation is such as to fall within the limits of visibility. If we picture such vibrating systems momentarily formed, it is easy to see that by their collision one with another they may acquire in a secondary way increased translational motion, and so lead to a state of things where the greater part of their energy is degraded in the form of heat. The high temperature of a flame would then be a consequence rather than a cause of its light.

This subject of the mechanism of luminosity, however, like so many others, has now become involved with the theory of electrons, and a chemist may be excused if he hesitates to pursue the subject further. Some years ago I called attention to the scantiness of our knowledge of the chemical changes that take place when metallic salts are used in flames for the production of spectra. Though there was general agreement that, for example, the yellow flame produced by common salt was due to the liberation and glow of metallic sodium, there was no agreement as to how the sodium was set free.

Arrhenius, pursuing the analogy which exists between the laws governing matter in the gaseous state and in the state of dilute solution, had previously been led to the view that the electrical conductivity of flames containing salt-vapours was due to ionisation of the salt throughout the volume of the flame. It appeared possible, therefore, that the luminosity might be ascribed likewise to the metal separated in the ionic state.

Experimental investigation undertaken with a view to elicit information on this subject seemed to favour the view that the metal was reduced by chemical processes, and that it glowed in the un-ionised condition. Evidence seemed to point to the conclusion that, for example, when common salt is introduced into the flame of coal-gas the sodium chloride yields sodium by the conjoint action of steam and reducing gases; when liberation of the metal was prevented by adding a large quantity of hydrochloric acid to the flame the glow disappeared, but the conductivity was not always diminished. The fact that sodium salts, including the chloride, impart their characteristic glow to the flame of cyanogen and to other flames in which water is absent leads to some difficulty in finding a chemical explanation, and it must be admitted that a direct thermal dissociation of an alkaline halide or oxide is not out of the question. The interval of detachment of the metallic atom may be exceedingly brief, but it must be remembered that even so short a time as the interval between the molecular encounters in a gas at a high temperature is still sufficient for the emission of thousands of undisturbed characteristic vibrations. The experiments to which I have alluded have been followed up with great industry and success by Professor H. A. Wilson, who has added much to our knowledge of the electrical condition of the flames containing vaporised salts; but the question of the condition of the luminous gas is still far from being settled. Very interesting and important investigations have been carried out by Lenard, who has shown that the stream of luminous vapour produced from a sodium salt in a Bunsen flame is deflected in an electric field in such a way as to indicate that the vapour is positively charged; but he gives reason for believing that the charged condition is intermittent with the neutral condition. The lines in the spectrum of an alkali metal are divisible, as is well known, into distinct groups or series, in each of which the oscillation frequencies corresponding with the lines are in a definite mathematical relationship. The principal series, which include the lines seen individually as such in ordinary flame spectra, are, according to Lenard, due to the electrically neutral atoms. In a salted spirit flame, and in other flames of low temperature where only lines of the principal series are represented, the stream of luminous gas does not behave in an electric field as if it were charged. In the flame of coal-gas burnt in a Bunsen burner the salt-vapour gives, in addition to the distinct lines of the principal series, diffuse bands of luminosity on the dark background, which, according to Lenard, represent the undeveloped subordinate series; and it is the atoms emitting these series that are deflected in the electric field. It is inferred, therefore, that the light in a salted Bunsen flame comes from different groups of centres of emission—the principal series from the neutral atom, and the lines of the first, second, and third subordinate series from atoms which have lost respectively one, two, and three electrons. Lenard goes further, and shows that the salt-vapour in a Bunsen flame, as in the flame of the electric arc, emits these different kinds of radiation from different structural regions; thus the vapour at the edge of the flame is electrically neutral and gives only the lines of a principal series.

The negative electricity in a salted flame would, according to Lenard, be disembodied, and recent experiments by Gold confirm the view that the negative carrier in flames is a free electron. In connection with this subject I ought to allude to an investigation by Tufts, which seems to throw some doubt on the conclusions which were drawn from the experiments made by Professor Wilson, Dr. Dawson, and myself; and I must also mention an important contribution to the subject recently made by Professor Hartley, in which considerable light is thrown upon the chemical changes undergone by compounds of the alkaline earth metals when they are introduced into flames, and upon the relation of these changes to the various spectral features. I am afraid, however, that it would be wearisome if I were to prolong this summary, and I must be content to leave it without doing justice to those who are engaged upon the work. The subject is obviously one of fundamental importance in relation to spectrum analysis, and my own slight connection with it has only strengthened my opinion that there is still a great deal connected with the genesis of spectra that requires the attention of the chemist even more than that of the physicist. Spectrum analysis arose under the joint influence of Bunsen and Kirchhoff, and I think its problems still call for more combined work on the part of chemist and physicist than has latterly been the custom.

The concluding passages of the address were devoted to a general consideration of the progress of chemical science. We hope to reproduce this in our next issue.

SECTION G.—ENGINEERING.

In the Engineering Section, Professor Silvanus P. Thompson, D.Sc., F.R.S., prefaced his address by a reference to the severe loss which the profession has so recently sustained by the death of Sir Benjamin Baker, and mention was also made of some of the more important achievements of the celebrated

Digitized by Google

engineer. A memoir, entitled "A Theoretical Investigation into the Most Advantageous System of Constructing Bridges of Great Span," in which was set forth the theory of the cantilever bridge (afterwards practically applied in the construction of the Forth Bridge) the building of the great dam across the Nile at Assouan, and his work in connection with the working of the internal railways of London (notably the later developments of deep-level tubes) would, the President said, always serve to perpetuate the memory of Sir Benjamin Baker.

Professor Thompson opened his address with a somewhat rosy account of the development of engineering in relation to the material resources of civilisation. Much that he said about the social and industrial conditions at different periods of history may be debatable, yet his statement of the position and importance of the engineer may generally be accepted :— "We must not delude ourselves with imagining that the happiness and welfare of mankind depend only on its material advancement ; or that moral, intellectual, and spiritual forces are not in the ultimate resort of greater moment. But if the inquiry be propounded what it is that has made possible this amazing material progress, there is but one answer that can be given—science. Chemistry, physics, mechanics, mathematics, it is these that have given to man the possibility of organising this tremendous development, and the great profession which has been most potent in applying these branches of science to wield the energies of nature and direct them to the service of man has been that of the engineer. Without the engineer how little of all this activity could there have been ; and without mathematics, mechanics, physics, and chemistry, where were the engineer ? "

THE INFLUENCE OF ABSTRACT SCIENCE UPON THE CONCRETE.

The interaction of abstract science and its application—in other words the influence of the abstract upon the concrete, was the subject of the address, and it was illustrated by a lucid and interesting account of the development of the electric motor. The idea that the progress of science ought to be an end in itself ; that scientific research ought to be pursued without regard to its immediate applications ; that the importance of a discovery must not be measured by its apparent utility at the moment—an idea which lay at the root of all Faraday's works—was a commonplace which, the lecturer said, could be admitted, yet it was true that the temperament of the discoverer counted for something. If so, then, as there are scientific persons who simply cannot work without the definiteness of aim that is given by a practical problem awaiting solution—Willanses as well as Regnaults, Whitworths as well as Poissons—then this idea needed modifying, and the world needed both types of investigator as well as the man who, making no claim to original discovery, by patient application and intelligent skill turns to industrial fruitfulness the results already attained in abstract discovery.

The reflex influence of industrial applications was shown to be a potent force in scientific progress by the invention of the telescope and the desire to perfect it, and their result in the work in optics of Newton, Huygens and Euler. It is well known that the quest of the Philosopher's Stone and the Elixir of Life laid the foundations of chemistry. Photography has immeasurably assisted meterology, ethnology, astronomy, zoology, and spectroscopy. The steam engine compelled attention to the laws of heat, while the mariner's compass gave rise to the wonderful structure of electrical science. The illustration from the discovery of the electric telegraph was treated at some length as furnishing a very striking example of this reflex influence. It was shown that the inventions of Cooke and Wheatstone in England, and of Morse and Vail in America, which were the outcome of the researches of Volta, Oersted, Sturgeon, Henry, and a host of less famous workers, gave a powerful incentive to a thorough investigation for a rational system of electrical and electromagnetic units. Had there been no telegraph industry to force electrical measurement and theory to the front, there would probably have been no work of Clerk Maxwell, nor the far-reaching researches of Hertz, nor wireless telegraphy. Lord Rayleigh maintained that the invention of the telephone compelled electricians to understand the principle of self-induction. In considering this reflex influence of the industrial applications upon the progress of pure science it is of some significance to note that for the most part this influence is entirely helpful. There may be sporadic cases where industrial conditions tend temporarily to check progress by imposing persistence of a particular type of machine or appliance ; but the general trend is always to help to new developments. The reaction aids the action ; the law that is true enough in inorganic conservative systems, that reaction opposes the action, ceases here to be applicable, as indeed it ceases to be applicable in a vast number of organic phenomena. It is the very instability thereby introduced which is the essential of progress. The growing organism acts on its environment, and the change in the environment reacts on the organism—not in such a way as to oppose the growth, but so as to promote it. So is it with the development of pure science and its practical applications.

In further illustration of this principle, reference was made to the immense effect which the engineering use of steel has had upon the study of the chemistry of the alloys. And the study of the alloys has in turn led to the recent development of metallography. Through the study of the intimate structure of metals, prompted by the needs of engineers, we are within measurable distance of arriving at a knowledge of the secret of crystallogenesis. Everything points to the probability of a very great and rapid advance in that fascinating branch of pure science at no distant date.

THE DEVELOPMENT OF THE ELECTRIC MOTOR.

There is, however, one last example of the interaction of science and industry which may claim closer attention. In the history of the development of the electric motor one finds abundant illustration of both aspects of that interaction. Going back to the year 1821, when Faraday, after studying the phenomena of electromagnetic deflexion of a needle by an electric current (Oersted's discovery), first succeeded in producing continuous rotations by electromagnetic means, the first signs of an electric machine are to be noted. This simple apparatus consisted of a piece of suspended copper wire, carrying a current from a small battery, and dipping at its lower end into a cup of mercury, rotated continuously around the pole of a short bar-magnet of steel placed upright in the cup. This apparatus was the merest toy ; nevertheless it demonstrated the essential principle, and suggested further possibilities. Two years later, Barlow, using a star-wheel of copper, pivoted so that the lowest point of the star should make contact with a small pool of mercury, found that the star-wheel rotated if a current was sent through the arm of the star while the arm itself was situated between the poles of a steel horse-shoe magnet. Shortly afterwards Sturgeon improved the apparatus by substituting a copper disc for the star-wheel. The action was the same. A conductor, if placed in a magnetic field, is found to experience a mechanical drag, which is neither an attraction nor a repulsion, but a lateral force tending to move it at right angles to the direction of flow of the current and at right angles to the direction of the lines of the magnetic field in which it is situated. Two years later came the announcement by Sturgeon of the invention of the soft-iron electromagnet, one of the most momentous of all inventions, since upon it practically the whole of the constructive part of electric engineering is based. For the first time mankind was furnished with a magnet the attractive power of which could be increased absolutely indefinitely by the mere expenditure of sufficient capital upon the iron core and its surrounding copper coils, and the provision of a sufficiently powerful source of electric current to excite the magnetisation. Furthermore, the magnet was under control, and could be made to attract or to cease to attract at will by merely switching the current on or off ; and, lastly, this could be accomplished from a distance, even from great distances away. How slowly the importance of this discovery was recognised is now a matter for astonishment. To state that Sturgeon died in poverty twenty-six years later is sufficient to indicate his place among the unrequited pioneers of whom the world is not worthy. Six years elapsed, and then there came a flood of suggestions of electric motors in which was applied the principle of intermittent attraction by an electromagnet. In a masterly memoir, Jacobi, from the results of some experiments, laid down a few years later the theory of electric motive power. But in the intervening period, in 1831, Faraday had made the cardinal discovery of the mechanical generation of electric currents by magneto-electric induction, the fundamental principle of the dynamo, a discovery not made use of till some thirty years later, when magneto-electric machines were made of a sufficient size to be of practical service in telegraphy, although none were built of a sufficient power to furnish a single electric light until about the year 1857. In the meantime, in America, Page had constructed a machine which had an iron plunger drawn by electromagnetic attraction into a hollow coil of copper wire, thereby driving a shaft and fly-wheel through the intermediate action of a connecting-rod and crank. Page's was, in fact, an electric engine, with 2-foot stroke, single-acting, of between 3 and 4 horse-power, and according to him consuming zinc at the rate of 3 lb. per H.P.

Digitized by Google

Upon the state of development of electric motors fifty years ago information may be gleaned from an exceedingly interesting debate at the Institution of Civil Engineers upon a paper read on April 21, 1857, "On Electromagnetism as a Motive Power," by Mr. Robert Hunt, F.R.S. In this paper the author states that there does not appear to be any nearer approach to a satisfactory result than there was thirty years ago. He admits that electro-magnets may be constructed to give any desired lifting power; but he finds that the attractive force on the iron keeper of a magnet of his own, which held 220 lbs. when in contact, fell to 36 lbs. when the distance apart was only one-fiftieth of an inch. To this rapid falling off of force, and to the hardening action on the iron of the repeated vibrations due to the mechanical concussion of the keeper, he attributed the small power of the apparatus.

In the discussion which followed, several men of distinction took part. Professor William Thomson, of Glasgow (Lord Kelvin), wrote, referring to the results of Joule and Scoresby: "These facts were of the highest importance in estimating the applicability of electromagnetism, as a motive power, in practice; and, indeed, the researches alluded to rendered the theory of the duty of electro-magnetic engines as complete as that of the duty of waterwheels was generally admitted to be. Among other conclusions which might be drawn from these experiments was this: that, until some mode of producing electricity as many times cheaper than that of an ordinary galvanic battery as coal was cheaper than zinc, electro-magnetic engines could not supersede the steam engine." Professor Tyndall agreed with the last speaker, but suggested that there might be some way of mitigating the apparent diminution of power due to the induction of opposing electromotive forces in the machine itself. In short, the most eminent engineers in 1857 condemned the idea of electric motive power as unpractical and commercially impossible.

Fifty years have passed. Hunt, Grove, Smee, Tyndall, Cowper, Joule, Bidder, Stephenson have long passed away. Kelvin remains the sole and honoured survivor of that remarkable symposium. But the electric motor is a gigantic success. It may be asked what has produced this great change. The answer may be given in terms of the action and reaction of pure and applied science. Pure science furnished a discovery; industrial applications forced its development; that development demanded further abstract investigations. The development of the dynamo for electrotyping and electric light produced the motor. Antonio Pacinotti, in 1864, laid down the principle of reversibility of action in a motor. From 1860 to 1880 the dynamo was being developed by Gramme, Wilde, Siemens, and Crompton, and proved a better motor than the earlier machines. Latterly the question of efficiency has been fully treated. The 50% efficiency idea of the eighties has gone, and now it can be said that the dynamo, within its class, is a more perfect machine than the steam engine.

The final portion of the address dealt with the education and training of engineers. Inter-play of action and reaction, the lecturer said, make for the development of the individual engineer. If properly trained, in him pure theory becomes an aid to sound practice; and practical applications are continually calling him to resort to his theories. Progress in this direction has extinguished the so-called practical man and the pure theorist. Here the lecturer digressed into the consideration of the mathematician and his relation to engineering practice. The idea conveyed may be epigrammatically stated as, "Better a living Whitworth scholar than a dry-as-dust Cambridge wrangler."

Some remarks on pupil apprenticeship, which bought the address to a close, are worth recording:—"One evidence of the wholesome change of opinion that is springing up concerning the training of engineers is the abandonment of the system of taking premium pupils into works with no other test or qualification than that of the money-bag. Already many leading firms of engineers have been finding that the practice of taking sons of wealthy parents for a premium does not answer well, and is neither to their own advantage nor in many cases to that of the "pupil," whom it is nobody's particular business in the shops to train. Premium pupilage is absolutely unknown in the engineering firms of the United States or on the Continent of Europe. The firms who have abandoned it are finding themselves better served by taking the ablest young men from the technical schools and paying them small wages from the first, while they gain experience and prove themselves capable of good service. Messrs. Yarrow and Co. have led the way with a plan of their own, having three grades of apprenticeship, admission to which depends upon the educational abilities of the youths themselves. Messrs. Siemens have adopted a plan of requiring a high preliminary training. The Daimler Motor Company has likewise renounced all premiums, preferring to select young men of the highest intelligence and merit. Messrs. Clayton and Shuttleworth have quite recently reconstructed their system of pupil-apprenticeship on similar lines. The British Westinghouse Company and the British Thomson-Houston Company have each followed an excellent scheme for the admission of capable young men. Even the conservatism of the railway engineers shows signs of giving way; for already the Great Eastern Railway has modernised its regulations for the admission of apprentices. What the engineering staffs of the railway companies have lost by taking in pupils because of their fathers' purses rather than for the sake of their own brains it is impossible to gauge. But the community loses too, and has a right to expect reform."

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

CONTINENTS AND OCEANS.

The President of this Section, Professor A. E. H. Lore, M.A., D.Sc., F.R.S., devoted his address to the consideration of the origin of continents and oceans. He said that if the ocean were to be dried up, the earth would still have a shape. What would it be? and why should the earth have that shape rather than some other? The key of the problem was put into our hands four years ago by Jeans, in his theory of gravitational instability. If there are any differences of density in different parts of a gravitating body, the denser parts attract with a greater force than the rarer parts, and thus more and more of the mass tends to be drawn towards the parts where the density is in excess, and away from the parts where it is in defect. In every gravitating system there is a tendency to instability. In a body of planetary dimensions this tendency, if it were not checked, would result in a concentration of the mass either towards the centre or toward some other part. But concentration of the mass means compression of the material, and it cannot proceed very far without being checked by the resistance which the material offers to compression. There ensues a sort of competition between two agencies: gravitation, making for instability; and the elastic resistance to compression, making for stability. Such competing agencies are familiar in other questions concerning the stability of deformable bodies. A long thin bar set up on end tends to bend under its own weight. A steel knitting-needle a foot long can stand up; a piece of thin paper of the same length would bend over. In order that a body may be stable in an assigned configuration there must be some relation between the forces which make for instability, the size of the body, and the resistance which it offers to changes of size and shape. In the case of a gravitating planet we may inquire how small its resistance to compression must be in order that it may be unstable, and, further, in respect of what types of displacement the instability would manifest itself. If we assign the constitution of the planet, the inquiry becomes a definite mathematical problem. The greatest difficulty in the problem arises from the enormous stresses which are developed within such a body as the earth by the mutual gravitation of its parts. The earth is in a state which is described technically as a state of "initial stress." In the ordinary theory of the mechanics of deformable bodies a body is taken to be strained or deformed when there is any stress on it, and the strain is taken to be proportional to the stress. This method amounts to measuring the strain or deformation from an ideal state of zero stress. If the ideal state is unattainable without rupture or permanent set or overstrain, the body is in a state of initial stress. The commonest example is a golf ball made of indiarubber tightly wound at a high tension. Now the problem of gravitational instability can be solved for a planet of the size of the earth on the suppositions that the density is uniform and the initial stress is hydrostatic pressure. If the resistance to compression is sufficiently small the body is unstable, both as regards concentration of mass towards the centre and as regards displacements by which the density is increased in one hemisphere and diminished in the other.

The shape of the earth is also influenced by another circumstance. We know that at one time the moon was much nearer to the earth than it is now, and that the two bodies once rotated about their common centre of gravity almost as a single rigid system. The month was nearly as short as the day, and the moon was nearly fixed in the sky. The earth must have then been drawn out towards the moon, so that its surface was more nearly an ellipsoid with three unequal axes than it is now. The primary effect of the ellipsoidal condition upon the distribution of continent and ocean would be to raise the surface above the

Digitized by Google

ocean near the opposite extremities of the greatest diameter of the equator. But, again, owing to the eccentric position of the centre of gravity, there would be an important secondary effect. The gravitational attraction of an ellipsoid differs from that of a sphere, and it may be represented as the attraction of a sphere together with an additional attraction. If the density was greater in one hemi-ellipsoid than in the other, the additional attraction would produce a greater effect in the parts where the density was in excess, and the result, just as in the case of rotation, would be a furrowing of the surface. It has been proved that the formula for this furrowing also is expressed by a spherical harmonic of the third degree.

Seismic and volcanic activities constitute the mechanism of the process of change. Their effect is cumulative, and, for this reason, they tend in the course of ages to transform the earth's shape from one definite type to another. The diminishing speed of the earth's rotation is another cause of change that appears to produce an alternating rather than a cumulative effect. The effect produced would be that of long periods during which the ocean would advance towards Arctic and Antartic regions, interrupted by shorter periods in which it would tend to retreat towards the equator.

SECTION L.—EDUCATIONAL SCIENCE.

THE APPLICATION OF SCIENTIFIC METHODS TO EDUCATIONAL PROBLEMS.

In the Educational Science Section, the President, Sir Philip Magnus, M.P., said that year by year new facts were recorded in different branches of inquiry, on which fresh conclusions could be based. The progress of past years, whether in Chemistry, Physics, or Biology, could be stated. Could the same be said, and in the same sense, of Education? It was true that the area of educational influence was being constantly extended. Schools of every type and grade multiplied, but was there any corresponding advance in our knowledge of the principles that should govern and determine our educational efforts, or which could justify us in describing such knowledge as science?

If we took science to mean organised knowledge, if we were to test the claim of any body of facts and principles to be regarded as science by the ability to predict, which the knowledge of these facts and principles would confer, could we say there existed an organised and orderly arrangement of educational truths, or that we could, logically, by any causative sequence, connect training and character either in the individual or in the nation? Could we indicate, with any certainty, the effects on either the one or the other of any particular scheme of education that might be provided? It was very doubtful whether we could say that educational science was, as yet, sufficiently advanced to satisfy these tests.

But although education might not yet fulfil all the conditions that justify its claim to be regarded as a science, we are able to affirm that the methods of science, applicable to investigations in other branches of knowledge, were equally applicable to the elucidation of educational problems. To have reached this position was to have made some progress, for we should see that if we are to succeed in arriving at fixed principles for guidance in determining the many difficult and intricate questions that arise in connection with the provision of a national system of education, or the solution of educational problems, we must proceed by the same methods of logical inquiry as we should adopt in investigating any other subject matter.

"Notwithstanding the progress we have made, it cannot be denied," continued Sir Philip, "that, in this country, there still exists a large amount of educational unrest, of dissatisfaction with the results of our efforts during the last thirty years. This is partly due to the fact that there is much loose thinking and uninformed expression of opinion on educational questions. No one knows so little as not to believe that his own opinion is worth as much as another's on matters relating to the education of the people. In this way statements, the value of which has not been tested, pass current as ascertained knowledge, and very often ill-considered legislation follows. In this country, too, the difficulty of breaking away from ancient modes of thought is a great drawback to educational progress. Suggestions for moderate changes, which have been most carefully considered, are deferred and decried if they depart, to any great extent, from established custom, and the objection to change very often rests on no historical foundation. Occasionally, too, the change proposed is itself only a reversion to a previous practice, which was rudely broken by thoughtless and unscientific reformers. The opposition which was so long raised to the establishment of local universities was largely due to want of knowledge on the subject; and certainly the creation, some seventy years ago, of a teaching University in London was actually hindered through a mere prejudice, which broader views as to the real purposes of University teaching and fuller information on the course of University development would have removed.

There never was a time perhaps when it was more necessary than now that education should be regarded dispassionately, apart from political bias, as a matter of vital interest to the people as a whole. Education nowadays is a question which affects not only the life of a few privileged, selected persons, but of the entire body of citizens. The progress that has been made during the last few years in nationalising our education has been very rapid. It may be that it has been too rapid, that sufficient thought has not been given to the altered social and industrial conditions which have to be considered. We have witnessed a strong desire and a successful effort to multiply Secondary and Technical Schools, and to open more widely the portals of our Universities. The object of the desire is good in itself. As the people grow in knowledge the demand for higher education will increase; but the serious question to be considered is whether the kind of education which was supplied in schools, founded centuries ago to meet requirements very different from our own, is equally well adapted to the conditions which have arisen in a state of society having other needs and new ideals. Very rightly our students in training for the profession of teachers are expected to study the writings of Locke, Rousseau, Milton, Montaigne, and others; but many are apt to overlook the fact that these writers had in view a different kind of education from that in which modern teachers are engaged, and that their suggestions, excellent as many of them are, were mainly applicable to the instructions to be given by a tutor to his private pupil, and had little or no reference to the teaching of the children of the people in schools expressly organised for the education of the many. Only recently have we come to realise that a democratic system of education, a system intended to provide an intellectual and moral training for all citizens of the State, and so organised that, apart from any consideration of social position or pecuniary means, it affords facilities for the full development of capacity and skill wherever they may occur, must be essentially different in its aims and methods from that under which many of us now living have been trained. It has also been brought home to us that the marvellous changes in our environment, in the conditions under which we live and work, whether in the field, the factory, or the office, have necessitated corresponding changes in the education to be provided as a preparation for the several different pursuits in which the people generally are occupied. Yet, notwithstanding these great forces which have broken in upon and disturbed our former ideals—forces the strength and far-reaching effects of which we readily admit, we still hesitate to face the newly arisen circumstances and to adapt our educational work to its vastly extended area of operation and to the altered conditions and requirements of modern life.

The problem of primary education is to teach by practical methods the elements of letters and of science, the art of accurate expression, the ability to think and to control the will; and the ordinary school lessons should be such as lead to the clear apprehension of the processes that bring the child into intimate relation with the world in which he moves. During the last few years the importance of such teaching has dimly dawned upon our educational authorities, but, instead of being regarded as essential, it has been treated as a sort of *extra* to be added to a literary curriculum, already overcrowded. What is known as manual training is to some extent encouraged in our schools, but it forms no part of the child's continuous education. It is still hampered with conditions inconsistent with its proper place in the curriculum, and is uncoordinated with other subjects of instruction. Moreover, no connecting link has yet been forged between the teaching of the Kindergarten and workshop practice in the school. We speak of lessons in manual training as something apart from the school instruction, as something outside the school course, on the teaching of which special grants are paid. Twenty or thirty years ago people used to talk about "teaching technical education," and from this unscientific way of treating the close connection that should exist between handwork and brain-work our authorities have not yet freed themselves.

At present all sorts of ideas are afloat which have to be carefully and scientifically considered. The working classes have to be further and somewhat differently educated, in order that they may better understand their own wants and how they are to be satisfied. We have placed vast powers in the hands of

Digitized by Google

local bodies, popularly elected—powers not only of administration, for which they are well adapted, but powers of determining to a very great extent, by the free use of the rates, the kind of instruction to be given in our schools, and the qualifications of the teachers to impart it. Moreover, these local bodies have shown, in many instances, a distrust of expert advice and a desire to act independently as elected representatives of the people, which cannot fail for some time at least to lead to waste of effort and of means. It was said years ago, when the centre of our political forces received a marked displacement, that we must educate our masters. Our masters now, both in politics and education, are the people, and it is only, I believe, by improving their education that we can enable them to understand the essential difficulties of the problems which they are expected to solve, and can induce them to rely, to a greater extent than they do at present, on the results of the application to such problems of scientific method, founded on the fullest information obtainable from historical and contemporary sources.

In conclusion, Sir Philip referred to the acknowledged condition of chaos in which secondary education was at present in the Board Schools. If we constructed a system of primary education which would serve equally for children of all classes—apart from social conditions—many of the present difficulties confronting the Board of Education would disappear.

INDIA AS AN IMPROVING MARKET FOR CHEMICALS.

OUR Indian correspondent writes:—"Now that the systematic destruction of rats and the disinfection of towns and houses are among the general precautions being taken throughout India on account of the plague, and also the strides in improved sanitation, suitable chemicals are finding a ready sale. As most chemical manufacturers are endeavouring to capture this gigantic trade, under improved conditions, a bird's eye view of India may be interesting, especially to those manufacturers who have appointed 'sale' agencies to look after their interests. The area of the Bengal Presidency is 122,392,054 acres, with 142 towns, 137,489 villages, 9,935,185 occupied houses, and a population of 50,722,067 persons. The Bombay Presidency has 85,565,952 acres, 202 towns, 25,699 villages, 3,490,715 occupied houses, and a population of 18,559,561. The Madras Presidency has 96,821,342 acres, 234 towns, 54,610 villages, 7,127,014 occupied houses, and a population of 38,209,436. The United Provinces of Agra and Oudh have an area of 72,454,762 acres, 453 towns, 105,068 villages, 8,684,860 occupied houses, and 47,691,782 persons. The Punjab has 86,748,004 acres, 171 towns, 32,663 villages, 3,212,734 occupied houses, and a population of 20,330,339. Burma has 107,009,469 acres, 52 towns, 60,395 villages, 2,092,811 occupied houses, and 10,490,624 persons. The Central Provinces have 74,174,539 acres, 102 towns, 37,905 villages, 2,500,724 occupied houses, and 11,991,670 persons. Eastern Bengal and Assam have 72,000,000 acres, 61 towns, 91,760 villages, 5,870,796 occupied houses, and 30,961,459 persons. Compare these huge areas with England, which has an area of 32,595,312 acres only. What a gigantic field for the British chemical industry, and for the exploitation of suitable fertilisers, disinfectants, rough chemicals, etc., etc."

Roburite Explosives Co., Ltd.—The directors have declared an interim dividend on the preference shares at the rate of 10% per annum for the six months to June 30.

South African Shipping Freights and Rebates.—The Agent-General for the Cape of Good Hope is instructed to notify that in consequence of the altered shipping freights to South African Ports, the various South African railway administrations have decided that rebates shall be given of the difference between freights before and after 1st July last on goods shipped from Europe by the Conference Lines, and forwarded direct from ship or bond at Cape Town, Port Elizabeth, or East London, and on goods from open stocks at the same ports, provided they are packed in original and unbroken packages, to the following areas in the Orange River Colony and the Transvaal. Orange River Colony.—Edenburg—Viljoen's Drift, including Winburg, Heilbron and Parys branches. Blœmfontein—Bethlehem, including Ladybrand and Maseru branches. Kroonstad—Bethlehem. Transvaal.—Vereniging — Springs — Pretoria—Vierfontein—Zerust. Rebates will be paid by the Goods Superintendents of the several railway administrations

Continental Notes.

IN the *Journal für Gasbeleuchtung* for July 27, an account is given of an ingenious research carried out by R. Ladenburg to ascertain the temperature of the incandescent particles of carbon in luminous flames. The temperature of a luminous body can, if it is absolutely black, be calculated, if it is known for what wave-length the emission of energy is the maximum. For this purpose it is necessary to examine the spectrum by means of a quartz prism and thermopile, and plot the results against the wave-lengths. If, however, the incandescent body is not black, but radiates some rays less readily than others, it is necessary also to determine this selective emission and correct the curve accordingly to what it would be for a black body. The selective emission of the carbon particles of a flame cannot be ascertained directly, but the selective absorption can, and this is practically identical. Ladenburg has measured the absorption by throwing the light from a Nernst lamp through a flame and measuring the energy radiated by the Nernst lamp and the flame separately and both together. By this means he finds that the maximum radiation for a "blackened" flame of a Hefner lamp is at $\mu = 1.75$, and of an acetylene flame at $\mu = 1.39$. Hence the temperatures of the carbon particles in these flames are 1,405° C. and 1,842° C. respectively. The temperature can also be calculated by taking the radiation at any selected wave-length and correcting for selective radiation. The results obtained in this way are in excellent agreement with those just mentioned, as also are measurements by Kurlbaum and Nichols, although the latter refer to the temperature of the acetylene flame itself, and not to the incandescent carbon particles.

The experiments carried out by Waidner and Burgess, at the American Bureau of Standards, to ascertain the reason of the advantageous results obtained with the new metallic electric incandescent lamps, are also described in the same issue. The authors find that the diminished consumption of current per candle power is partly due to the far higher temperatures that they can stand before they melt or disintegrate, as compared with the carbon filament, and partly to selective radiation. Tungsten, for instance, melts at 3,200° C., and does not form a deposit upon the glass even when the lamp is burnt out. The authors have found the specific watt consumption with carbon lamps to be 3 to 4 watts per candle-power, with the tantalum lamp 2 watts, and with the wolfram lamp 1 watt. With the arc lamp a very high temperature is attained, but the emission of light is not so very good, partly because much of the heat is lost by conduction and convection, and partly because the carbon rods themselves intercept much of the light.

In the *Chemiker Zeitung* for July 17, H. Pleyer and B. Wagner give an account of some remarkable springs that have been found in a coal mine in Silesia. Some of the springs contain free sulphuric acid, and others barium sulphide. The authors discuss the slow chemical changes that may have caused the formation of these substances.

In the same issue, M. Siegfeld gives an account of the chemistry of milk and dairy produce in 1906, and W. Gossling publishes a paper on dialkyl barbituric acids.

The issue of July 20 contains a paper by Cross, Bevan, and Briggs on the formation of lignone phloroglucide without colour reaction. There is also an account of a milk colorimeter, by A. Bernstein.

In the issue of July 24, W. Ostwald contributes a very interesting paper on the transmutation of the elements. Ramsay's discovery of the conversion of radium into helium has now been fully confirmed and established. Ramsay, however, has not stopped there, but has been investigating several other even more remarkable cases of transmutation of elements, and he believes he has established the conversion of copper into lithium. Radium emanation, moreover, is able to give rise to several different elements. If it is allowed to stand by itself or with hydrogen, it produces helium, but if the emanation is in contact with water, neon is formed, together with quite small traces of helium, and if the water contain a salt of a heavy metal, such as silver nitrate or copper sulphate, xenon is the product. But in addition to these gases belonging to the series of no valency, there are other products which, however, are formed in such exceedingly minute quantities that it is only by the skill of such a master as Ramsay that they could be discovered. The elements that have thus been observed in

Digitized by Google

quantities of the order of 0.001 mg. are lithium, sodium, and calcium, although as regards the last two there is a possibility that they have been derived from the walls of the vessels used. These discoveries are of the most fundamental importance, as they demonstrate that the law of the conservation of the elements is by no means absolutely true, but only applies to certain conditions. And it raises the question whether the other similar natural laws have any greater degree of absolute truth: namely, the laws of the conservation of mass, energy, and momentum. Ostwald is of the opinion that although these laws are true within the limits of experimental error under ordinary conditions, they are not absolutely true in cases where there is any development of radiation. As there are always rays given off to some extent whenever there is chemical or physical change, creation and destruction of energy, etc., must be taking place everywhere and at all times, though only in extremely minute quantities.

ADULTERATION IN INDIA.

COMMERCIALLY recognised adulteration of Indian products and produce, although strongly denounced by officials, continues to go on. The producer frequently supplies a pure article, but "merchant shippers" and middlemen wilfully add an admixture before exporting, their excuse for so doing being "trade custom," and "because buyers in England refuse to pay the price of the pure article!" Various adulterants are used. To one staple Indian product of which about 1,000,000 tons are annually shipped is added an admixture of dirt, roughly 40,000 tons in the proportion of 193 to 7. This admixture is commercially recognised. One port alone supplies 20,000 tons of this dirt, and it is estimated that if the practice goes on for a century, the town will cease to exist! Outside a large town recently, a crowd of natives were observed to be carefully sifting and sieving clods of earth. On being asked the nature of the "new industry," they replied, that the sifted earth was in great demand in the town for mixing with products before "merchants" sold them, whilst at a goods station a group of natives were hard at work mixing mud and water for exported articles. Government officials recommend buyers to accept only the pure article, which would soon stop the "merchants'" practice of adulteration, and also the custom being commercially recognised.

GRANTS TO UNIVERSITIES.—On the recommendation of an Advisory Committee appointed in January last year the Treasury have sanctioned a reallocation of the grants to colleges giving university education, which reduces the grant to Victoria University of Manchester from £12,000. to £10,000. The report of the Committee has been issued as a Blue-book on Thursday, and it states that when the Committee recommended the Treasury to continue for the year 1906-7 the scale of grants adopted for 1905-6 they emphasised the strictly temporary character of the allocation then continued, and in view of the complexity surrounding the question of State grants the Committee now recommend, and the Treasury have agreed, that the period for which the present reallocation is to remain in force should be shortened from five years to two, so that a fresh reallocation may take place from April 1, 1909. For the purposes of the provisional allocation a financial test, as on previous occasions, was adopted to measure the position of each college from a purely quantitative point of view. The results so obtained were compared with the results obtained five years ago; and finally the Committee considered the special circumstances of each of the colleges in connection with the reports of inspectors who visited them. The Committee add:—"The Treasury minute of April 5, 1907, instituted the rule that no grant to any college should exceed one-fourth of the local income, and that the maximum grant should be £3,000. With the increase in the total sum available for grants these conditions have been abandoned. We think it advisable, however, that a new maximum limit for all grants should be set up, and we would suggest £10,000. as a suitable amount. This maximum would relate only to the annual grants for general purposes and would be exclusive of grants for special purposes which might be made from time to time."

THE JULY TRADE RETURNS.—The Board of Trade returns issued on Thursday show that the imports for July amounted to £52,213,304., compared with £48,607,799. in the corresponding period of last year, an increase of £3,605,505. The exports for the month were £40,452,331., against £33,442,962., an increase of £7,009,369.

Indian Notes.

Sanitary affairs are about to be handled in a scientific and skilled manner by a new Sanitary Engineer's Service.

The Government of India has approved of the revised rules in connection with specialist appointments, which number 105.

A remedy is sought for the biting-fly (*tabanus*) which causes *surra*, a most destructive disease among camels. India possesses 381,734 camels.

A chemical preparation for entirely destroying roots, vegetation, and weeds in walls, buildings and roads, retails at Rs.12.8. (*i.e.*, 16s. 8d.) per 5 gallon drum.

A remedy is sought for the beetle pest in the cocoanut fields in Ceylon. It is regarded as "the danger of the future." The area under cocoanuts in Ceylon is 880,409 acres.

During the official year just closed, 120 explosive licences were granted in India, and 235 inspections were made. No accidents occurred during the year in magazines or explosive factories.

Ceylon planters are retailing rubber seeds, August delivery onwards, *Hevea Braziliensis*, from 7 to 18 year old trees at Rs.5.0. per 1,000 seeds; and Para rubber seeds from 8 to 16 year old trees at the same price.

"The greatest living authority on manganese mining" has left Europe for India, to report on the opening up of mines, and to advise on the practicability of developing them "on a scale hitherto unattempted."

The Government Laboratory at Muktesar, near Naini Tal, has been very successful with its vaccines and prophylactics, the demand being great, not only from India, but from Burma, Ceylon, and the Straits Settlements.

The United Provinces Government has decided that an opportunity should be given for demonstration, on a commercial scale, of the Schrottky process of indigo manufacture, and the necessary quantity of the Java-Natal plant will be sown next cold season.

Six hundred and twenty applications to file patent specifications were made during the past year. Of these 209 were made by residents in India (of which 65 were from natives) and 411 were from abroad. From the latter source 194 came from the United Kingdom, 77 from the United States, 53 from British Colonies, 26 France, 25 Germany, etc.

A large industry could be built up in India in the extraction of essential oils and the manufacture of perfumery. Already, methods of a crude nature and manufacture on a small scale are in operation. A modern enterprise is needed, with up-to-date apparatus, together with chemists possessing expert knowledge. There is money in the scientific manufacture of perfumery, and India is a large consumer.

The total revenue derived from salt in Burma during last year was Rs.3,88,291. from locally produced salt, and Rs.12,64,380. from imported. Locally produced salt totalled 812,496 maunds, or 100,000 maunds in excess of the previous year. A point now engaging attention is the amount of wastage which should be allowed in respect of salt stored in warehouses. At the moment the local official may make such allowance as he thinks fit. Some suggest a 15% allowance.

MANCHESTER SHIP CANAL CO., LTD.—Mr. J. K. Bythell, presiding on Thursday at the half-yearly meeting of the Manchester Ship Canal Company, said the traffic of the port during the past half-year had been considerably larger than in previous corresponding periods, and that the total amount for distribution was £130,898. The shareholders must be prepared for considerably increased expenditure, particularly in the matters of labour and coal. He was far from pessimistic with regard to the future. In 1894 they carried 686,000 tons, and in the past year 4¾ million tons, and these figures left no room for depression. Mr. Bythell made an appeal for more extended support on the part of the traders of Manchester and the district.

STANDARD OIL LITIGATION.—On Saturday last, the Judge of the United States District Court at Chicago inflicted on the Standard Oil Company fines amounting to £5,848,000., being the maximum penalty for 1,462 violations of the anti-rebate law, of which the company had been convicted in its dealings with the Chicago and Alton Railway. The Judge condemned the conduct of the officials of the company in strong terms, and announced that the violations of the law would be investigated from the point of view of a conspiracy between the Standard Oil Company, the Chicago and Alton Railway, and their Officials.

Selected Correspondence.

THE PRICE OF PETROL.

To the Editor of the Manchester Guardian.

Sir,—Sir Marcus Samuel, on July 29, addressing the shareholders of the "Shell" Company, is reported to have said: "Supplies of petrol are to-day so ample that . . . there is not the remotest danger of any failure of petrol supplies." He went on to say that he viewed with "amusement" the suggestion of the Motor Union that there was a possibility of a shortage in the supply.

The users of motor cars, however, cannot share the "amusement" of Sir Marcus Samuel when they know that between November 1904, and December, 1906, the price of petrol to the retail agent was increased from 7d. to 1s. 1d. per gallon. The unfortunate consumer is therefore entitled to ask (and perhaps Sir Marcus will explain) why it is that, in spite of the fact that "in Koetei alone we have proved territory, extending over a length of more than 60 miles, containing anticlinals of oil throughout the entire area," the distributing companies have put up the price of petrol 85% in two years.

Sir Marcus, however, made a statement which goes far to prove the need for the warning which the Motor Union has given. Petrol spirit forms on the average about 5% of the crude petroleum, and Sir Marcus states that "the price will necessarily depend upon whether we and other producers with whom we have to compete are obliged to produce crude oil for the sole purpose of making petrol, or whether, as at present, we can find remunerative markets for the other products which are left when the petrol is removed from the crude."

The price, therefore, at which petrol can be sold depends upon the market for the 95% of residuals. The Motor Union have been authoritatively informed that the market for these residuals of which paraffin is the most important, is on the decline. Is Sir Marcus prepared to assert to the contrary?

If, as he appears to think, it is within the range of possibility that one day he will be "compelled to produce crude oil for the sole purpose of making petrol," or, in other words, to waste 95% in order to obtain 5% of saleable product, will he deny that the shortage of petrol will be very real and the price very high? Possibly a chemical process is known to Sir Marcus Samuel which will make it financially possible to increase largely the production of petrol obtainable from the crude, and, having in the matter of this knowledge the advantage of the rest of the world, it may have justified him in speaking with such confidence.

May I venture to suggest to Sir Marcus that he has overlooked in his speech the recommendation of the Committee to motorists as to the need for using petrol spirit of a greater specific gravity and for inventing and using a carburetter which will burn paraffin? If this is is done the "Shell" Company will be able to dispose of the over-stocks of residuals and sell petrol in consequence at a reduced rate.—Yours, &c.,

W. Rees Jeffreys.

1, Albemarle-street, London, W.

Nitrate Statistics.—The Permanent Nitrate Committee, in their public statistical circular for August, state the shipments of nitrate of soda as follows:—(1.) Total exports to Europe, July, 2,293,600 quintals. (2.) Imports, Europe, July, 40,050 tons. (3.) Deliveries, Europe, July, 53,300 tons. (4) Visible supply, Europe, 1st August:—Stocks and afloat, 341,980 tons.

Russian Platinum Production.—According to the *Soloto y Platina*, the cause of the fall in the price of platinum is to be found in the action of the Successors of Count Schouvaloff, who, it is alleged, are taking advantage of some delay in payment on the part of the French buyers (who held the contract for the production of the Krestovosdvishensk mines over a long series of years at a low price), in order to cancel the bargain. This it is said has provoked the French Company to run down prices, so as to induce the Schouvaloff Company to reinstitute the contract, on the original terms. The situation, if correctly described, is a very interesting one, as the Russian platinum producers have been agitating vigorously to stop the export of unrefined platinum, and to refine the metal in Russia. The action of the Schouvaloff house appears to be a vigorous step in the direction indicated.

IRON CARBONYLS.*

By Sir James Dewar, M.A., D.Sc., F.R.S., and H. O. Jones, M.A., D.Sc.

Iron pentacarbonyl $Fe(CO)_5$ is a yellow liquid which resembles nickel tetracarbonyl in its chemical and physical properties, but it is more stable towards chemical reagents. When decomposed by reagents it always gives rise to *ferrous* salts.

The most striking difference observed between its behaviour and that of nickel carbonyl is due to the action of light, iron pentacarbonyl being decomposed with evolution of carbon monoxide and formation of an orange crystalline solid, *diferro-nonacarbonyl*, $Fe_2(CO)_9$. This change is supposed to take place in two stages, represented by

$Fe(CO)_5 = Fe(CO)_4 + CO$ and $Fe(CO)_4 + Fe(CO)_5 = Fe_2(CO)_9$

since when iron pentacarbonyl is dissolved in nickel carbonyl it is not affected by light, due, it is suggested, to the formation of an unstable compound, $FeNi(CO)_9$.

The decomposition induced by light is reversed slowly in the dark. Above 56° C. light has no action on iron pentacarbonyl: this is explained by supposing that the direct action induced by light is a change that is almost unaffected by temperature, like the reaction between ferric chloride and oxalic acid and some other photochemical actions, whereas the reverse action of carbon monoxide and the diferro-nonacarbonyl has a normal temperature coefficient.

When diferro-nonacarbonyl is heated alone a dark green liquid is produced: this consists chiefly of iron pentacarbonyl; on continued heating the green colour disappears and iron is deposited; the change is then represented by the equation $2Fe_2(CO)_9 = 3Fe(CO)_5 + Fe + CO$.

When substances like hydrocarbons or ether are present in excess, and the temperature is not allowed to exceed 100° C., an intensely green-coloured solution is obtained; no solid is deposited, and no gas is evolved. The dark green solution under suitable conditions deposits dark green lustrous crystals which represent a third compound of iron and carbon monoxide, *iron tetracarbonyl*, $Fe(CO)_4$, which has a high molecular weight. When alcohol or pyridine is used as solvent in which to heat the diferro-nonacarbonyl the solution obtained is red, and no solid could be obtained from these solutions.

Iron tetracarbonyl is very stable towards reagents: it dissolves in most organic solvents to give dark green solutions which exhibit a characteristic absorption band in the yellow. In pyridine and alcohol, however, the colour of the solution is green at first, but changes slowly on standing and quickly on warming to a deep red; the red solutions show no selective absorption.

Both diferro-nonacarbonyl and iron tetracarbonyl, when decomposed by reagents such as concentrated sulphuric acid, give carbon monoxide and *ferrous* salts.

*Abstract of a paper read before Section B of the British Association Leicester Meeting.

The Force Cragg Mines, Braithwaite, near Keswick, which were worked some thirty years ago, are being reopened. Sulphate of barytes was then mined, but this was discoloured and needed bleaching. The low price of blende at that time prohibited raising, but this mineral is now being mined. Upon the Eskdale Fells, large quantities of arsenical pyrites carrying nickel have been found, and it is reported that these will be worked at an early date.

South Metropolitan Gas Co.—The report for the half-year to June 30 states that the great increase in the cost of coal under the new contracts and in the rates has compelled the directors to increase the price of gas from midsummer from 2s. to 2s. 3d. per 1,000 ft. The dividend payable at a 2s. 3d. price is 8s. per cent., or £25,700, a year, less than with the price at 2s. More than three-fourths of the coal used in the half-year was under last year's coal contracts, while the receipts from products were better all through the half year, and there was an increase of 2.6% in the gas rental. Thereby the deficiency of £9,364, on the December accounts has been made up, and there is a small balance to carry forward. The directors therefore recommend the same dividend as has been paid for several years past, namely, at the rate of 5½% for the half-year. The dividend payable next time will be at the rate of £5. 6s. 8d.%.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 8d. *in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery-lane, W.C.*

1906.

Coupled Gas Producers. Mason's Gas Power Co., and Wright. 16,218.
Artificial Fuel. Grayson. 16,977.
Treatment of Zinc Residues. MacIver and Fradd. 17,001.
Extraction of Tin from Ore. MacIver and Fradd. 17,002.
Cement Manufacture. Timofeeff. 17,006.
Cooling and Purifying Gases. Meyer and Hastert. 17,999.
Esters of Alcohols of Terpenes. Shukoff. 20,526.
Bunsen Burners. Oxman and Lusen. 21,817.
Extraction of Sulphur. Rohleder. 23,967.
Tertiary Butyl-xylene or Tertiary Butyl-toluene. Bloxam. 28,147.

1907.

Rotary Kilns. Shiner. 443.
Super-Alkalinated Dry Soap. Soc. Francaise "La Cremouline." 2,519.
Steam Superheaters. Pielock. 5,841.
Electrolytic Process of Copper Extraction. Thiret and Mage. 6,502.
Ore Washers or Concentrators. Wall. 7,801.
Disintegrating Machines. Jaquet. 9,555.
Extraction of Sulphur from Gangue. Boult. 11,187.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Method of Manufacturing Explosives. H. N. Wessel, 34, Kirkegaden, Christiania, Norway. British Patent, 2,286. (Date applied for under International Convention, February 7, 1906).

The inventor claims :—(1.) Method of rendering ammonium nitrate explosive with metallic ingredient easily detonisable in compressed condition, characterised by the addition and even distribution in the mass of the explosive of a suitable quantity of nitrocellulose. (2.) Explosives manufactured as firstly claimed. (3.) Explosives manufactured according to the method stated in claim (1), and containing :—nitrate of ammonium, 50-80%; ferrosilicon, 5-20%; nitrocellulose, 5-25%; organic or free carbon, 0-10%; ammonium oxalate (chloride) 0-8%. (4.) Explosives as firstly claimed, with the addition of a suitable amount of black gunpowder, according to different requirements.

Improvements Relating to Electric Furnaces. S. Z. de Ferranti, 31, Lyndhurst Road, Hampstead, London. British Patent, 13,949. June 18, 1906.

This invention relates to electric furnaces of the general type described in Specification No. 700 of 1887.

The claims are :—(1.) An induction furnace operated by one or more phase current, and having energising or primary coils constructed of tubular form through which a cooling fluid is circulated. (2.) An induction furnace having means for preventing the iron of the magnetic circuit rising above the temperature at which the maximum permeability is obtained. (3.) An induction furnace operated by one or more phase current, and having a rotary or shifting magnetic field adapted to circulate or mix the molten metal. (4.) The furnaces described with reference to the drawings accompanying the specification.

Improvements Relating to Electric Furnaces. S. Z. de Ferranti, 31, Lyndhurst Road, Hampstead London. British Patent, 13,949a. June 18, 1906.

The claims of this specification are :—(1.) A two or more phase electric induction furnace having two or more cores grouped for the minimum loss. (2.) A two or more phase electric induction furnace, in which certain parts of the magnetic cores energised by currents of different phase are coalesced to reduce the length of the magnetic circuits and minimise loss. (3.) Improved electric induction furnaces substantially as described with reference to the drawings accompanying the specification.

Improvements in the Manufacture of Soap. J. C. A. Henderson, Bishopsgate Street Within, London. British Patent, 14,784. June 28, 1906.

This invention relates to a process for the manufacture of soap from cocoa-nut oil, and consisting in forcing ozonised air or ozonised oxygen through the cocoa-nut oil at a suitable temperature, until the oil loses its characteristic odour and gives an oxidising reaction with potassium iodide, and then saponifying the oil.

A New or Improved Discharging Apparatus for Superphosphate Pits. H. R. Neech, 20, Colegrave Street, Lincoln. British Patent, 17,512. August 3, 1906.

The apparatus consists of a horizontal base frame mounted on running wheels and having rear upstanding brackets provided with a transverse shaft carrying one or more drums or wheels, while pivoted to the transverse shaft is a forwardly extending frame carrying at its free end a transverse shaft, on which is mounted one or more drums or wheels corresponding with those on the rear shaft, around which drums or wheels are passed one or more endless chains or belts carrying a series of prongs or forks, and the pivoted frame is adjustably supported so that the forward end of the endless chain or belt, carrying the prongs or forks, is capable of being raised or lowered at will; while the endless chain or belt is driven by hand or by power, as desired.

In use, the forward end of the apparatus is lowered so as to pass within the open end of the pit, when, by operating the endless chain or belt, the prongs or forks thereon are caused to engage with the superphosphate and discharge it from the pit; while, by mounting the apparatus on running wheels, the entire apparatus can be moved to any position within the pit, to cause the prongs or forks of the endless chain or belt to engage and remove the superphosphate therefrom. The superphosphate can be dropped by the prongs directly on the ground; or, if desired, the apparatus can be provided with a conveyer belt or trough below the prongs, so as to receive the discharged superphosphate and carry it outward to a suitable position away from the mouth of the pit.

Improvements in the Treatment of Sulphuretted Hydrogen, or Gases Containing Sulphuretted Hydrogen, for the Obtainment of Sulphur therefrom. C. E. Tyers, J. Hedley, and the United Alkali Co., Ltd., all of 30, James Street, Liverpool. British Patent, 25,976. November 16, 1906.

For the purpose of obtaining sulphur from sulphuretted hydrogen, or gases containing sulphuretted hydrogen, the sulphuretted hydrogen, or gases containing it, have been mixed with air, and the mixture passed in contact with a substance such as bog iron ore, or bauxite, but the yields of sulphur have not been satisfactory. The inventors have found that the obtainment of the sulphur from sulphuretted hydrogen, or gases containing sulphuretted hydrogen, is more readily effected and a better yield obtained if, in place of contact substances such as bog iron ore and bauxite, the contact substance, or catalytic agent, is a salt, or ore, of titanium, or other titaniferous substance, either in the crude or in a prepared state; for instance, titanic iron ore, or rutile, may be used, or titanium oxide mixed with broken bricks, etc., or broken bricks, etc., impregnated with titanium chloride.

Improvements in the Manufacture of Alumina Compounds. Dr. E. Ludvig Rinman, Upsala, Sweden. British Patent, 15,590. July 10, 1906.

The inventor claims:—(1.) A process of manufacturing aluminium salts, consisting in heating an alumina-containing material with an ammonium salt, so that the acid of the ammonium salt produces the corresponding aluminium salt, with the generation of ammonia. (2.) The process of manufacturing aluminium sulphate, which consists in heating aluminium-containing material with ammonium sulphate to about 400° C., whereby aluminium sulphate is formed with the generation of ammonia.

Improvements in the Utilisation of By-Products Obtained in the Manufacture of Borax. The Liverpool Borax Co., Ltd., and Ambrose Fry, both of Rathbone Road, Liverpool. British Patent, 4,193. February 20, 1907.

In the manufacture of borax a by-product is formed known as borax-mud, and composed of magnesium carbonate, calcium carbonate and compounds of silica and soda, precipitated in the saturators. This borax mud from the saturators is taken after being freed from the mother liquors, and to it is added soluble alginates prepared from various classes of seaweed. The proportion of alginate may vary from 5% to 20%, preferably about 15%.

The borax mud and alginate are thoroughly and intimately mixed in a suitable mixing machine or mill, say for about 15 minutes, and sufficient water is added to reduce the material to a plastic or semi-plastic mass of about the consistency of ordinary plaster. To the material during mixing may be added any desired quantity of asbestos fibre, hair, or other fibrous substance to cause the material to bind more firmly together.

The material so produced has very low heat-conducting or absorbing properties, and may be used for covering steam boilers, steam pipes, etc., to prevent radiation of heat, or for other purposes.

CALCIUM: ITS PROPERTIES AND POSSIBILITIES.*

By Arthur E. Pratt, B.Sc., A.R.S.M.

General Properties.—Calcium is a silvery white metal readily oxidised in moist air. It is very light (sp. gr. 1.52), fairly malleable, has a high specific heat, and is a good conductor of electricity. It is about as hard as aluminium, but at 400° C. becomes as soft as lead. It is volatile, and can be sublimed *in vacuo* between 700° C. and 800° C., and melts at the latter temperature. It is a very powerful reducing agent.

Calcium Alloys.—The chief effects of alloying calcium with other metals are to produce brittleness, crystallisation, and hardness; to promote oxidation and disintegration on exposure to air; to confer the power of decomposing water, and in other ways increasing the chemical activity.

The author's experiments confirm Roberts-Austin's observation that the presence of small amounts of metals of high atomic volume will cause deterioration of the physical properties of metals of low atomic volume. The atomic volume of calcium is high (25.4), and the effect of small amounts on other metals is decidedly prejudicial, provided that the metals in question are pure. The experiments were conducted in a converse manner to Roberts-Austin's, *i.e.*, the constant was a metal of high atomic volume (calcium) instead of being low (gold). In the course of the work the following observations were made. When an alloy is made of calcium and some metal which possesses a chemical property in common with it, an increased activity in the manifestation of that property is noticed in the alloy. This increase appears to be greater than would be obtained by the simple admixture of a more active metal, the presence of calcium usually increasing the activity of the other metal. In some cases the alloy is more active than either of its constituents.

Further, the chemical properties of calcium appear to be more pronounced in an alloy with a metal having an atomic volume closely approaching that of calcium than they are in an alloy of the same percentage with a metal having a much lower atomic value. The two metals in question should be about equally active when unalloyed in the particular property with respect to which they are to be compared.

It is probable that both these principles are general, and not confined to calcium, although more extended research on these lines would be desirable.

* Abstract of a paper read before Section B of the British Association, Leicester Meeting.

Industrial Possibilities.—The most promising applications of calcium are as a reducing agent and for the refining of metals. In the latter case it acts in three distinct ways:—(1) By reducing oxides and sulphides; (2) by eliminating dissolved gases; (3) by forming compounds with certain impurities, thus rendering them less deleterious. All three modes of action are strikingly shown in the case of copper. A suitable addition of calcium will remedy "dry" or "sulphury" copper, give a sound casting, and give a soft and tough ingot with prohibitive proportions of bismuth or antimony, besides restoring ordinary overpoled copper to tough pitch. If excess of calcium is present, however, it induces brittleness on its own account.

With one or two doubtful exceptions, no alloy of calcium has shown any promise of commercial utility so far as physical properties are concerned, its only likely application in this direction being its hardening property.

The Professorship of Chemistry at the Handelshochschule, Berlin.—We are informed that Professor Binz has been appointed to the Chair of Chemistry at the Handelshochschule, Berlin. Professor Binz is 39 years of age, and early began his study of chemistry, passing from the Gymnasium of his native town, Bonn, through the universities of Manchester, London, Berlin, Gottingen and Leipzig. In the chemical industry he is well known as an authority on textile printing, dyeing and mercerising, and his work in connection with the manufacture of indigo and its applications is equally well known. Professor Binz is the author of several standard works, and he has contributed largely to periodical chemical literature.

BILLS IN PARLIAMENT.—The Government do not intend to proceed further with the Poisons and Pharmacy Bill. The Companies Bill and the Butter and Margarine Bill have been read a second time in the House of Lords.

THE INCOME TAX.—Mr. Corrie Grant has addressed a question to Mr. Asquith with regard to the right of income tax payers to claim the lower rate of 9d. in the pound, asking whether it is proposed that any person who has already made a return and does not receive the supplementary form will have to pay one shilling in the pound unless he applies for a supplementary form during the present month to the local surveyor. Mr. Asquith, in his reply, says that such is not the intention. Persons who are entitled to relief in respect of earned income, and who have not already made a return of their total income for the purpose of claiming the existing statutory abatements, will be required, as provided in the Finance Bill, to present their claims before September 30. Supplementary forms for this purpose will be issued by the surveyors of taxes to persons who appear to be entitled to relief immediately after the passing of the Finance Bill; but, as stated in reply to a question by Mr. Evelyn Cecil on July 19, it will be advisable for anyone so entitled who has not received a supplementary form by the end of the present month to apply to the surveyor for his district, who will see that the omission is repaired.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, July 23rd, 1906.

(Rate of Exchange, $4.87 = £1.)

Nitrate of soda remains firm, but not very brisk at $2.50. per 100 lbs. Sulphate of ammonia inclines to dulness, at $3.05. per 100 lbs. Grey muriate is 6c. to 6¼c., as to make, and is in fair demand. White electrical muriate is weak under plentiful offers, and ranges from 5¼c. to 6⅛. Lump carbonate of ammonia is 7¼c.' to 8c., and powdered nominally 1c. per lb. more. Lump sal ammoniac, good white seconds, is unchanged, at 9¼c. per lb. Bleaching powders are dull at $1.20. to $1.30. as to brand. Alkali is unchanged, at 92½c. per 100 lbs., f.o.r. makers' works for light 58% in bags. Caustic soda, 74%, is $2.05. per 100 lbs. Sulphate of copper is weak, at 7c., the present Syndicate quotation. White powdered arsenic is in fair demand for prompt delivery, at 7c. to 7¼c., while futures are offered at about the same range. Red Saxony arsenic is steady, at 7½c., with Silesian make somewhat less. Calcined carbonate of potash, 80-85%, is 3⅞c.; and hydrated, same test, 4¼c. Caustic potash, 75%, is 4½c. Chlorates are unchanged at the regular Syndicate prices. Bichromates are now controlled by convention, and soda is 7⅛c.; and potash, 8⅛c. Oxalic acid remains in good demand, at 8¼c. to 9c. for prompt delivery. Prussiate soda is 9⅝c., and potash 15⅝c. to 16c. Phosphate of soda is $1.85. per 100 lbs., in bags. Sulphide of soda is $1.35. per 100 lbs. Antimony products continue to decline; needle is now offered at 8c. on spot, while antimony salts, 47%, are quoted at 16c.

TAR AND AMMONIA PRODUCTS.

FRIDAY.

Benzols quiet, with values given at 8¼d. to 8½d. for 90's, and 9d. for 50-90's.

Crude tar, 15s. 6d. to 20s. per ton, Thames; 1¼d. to 1⅜d. per gallon delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d.; pitch (London), 26s., f.o.b.; Gas Company, 29s. to 30s.; East Coast, 25s. to 25s. 6d.; West Coast, 24s. to 24s. 6d. Carbolic acid, crude, 50%, 1s. 5¼d. to 1s. 5½d.; 60%, 1s. 7¼d. to 1s. 8d.; 75%, 1s. 11¾d. to 2s. Crystals, 39-40, 5¼d.; 34-35, 5⅝d. Cresylic, 95%, 1s. 1¾d. to 1s. 2d. Anthracene, 40 to 45% A, 1½d. to 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia dull. Nearest values are:—Beckton, £12. 2s. 6d.; Beckton terms, £11. 13s. 9d.; London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined 11s. 9d.; Liverpool ordinary, 11s., and refined, 11s. 3d. Official quotations:—Cargoes off coast or due, 11s. 3d.; ditto for prompt shipment, 11s. 6¼d.

FERTILISER MATERIALS.

FRIDAY.

Business throughout the past week has been of a holiday character. Mineral phosphates of all grades maintain a strong position.

Little interest is shown in East Indian bone meal for shipment, shippers being firm at £5. per ton, nett, c.i.f. terms Liverpool, for 4½ and 52% quality. On spot £5. 7s. 6d. to £5. 12s. 6d. per ton, ex store, is asked.

Nitrate of soda is very quiet, though prices remain steady, at 11s. 1½d. to 11s. 4½d. per cwt., ex store, according to quality.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: standard brands, £82. 10s. to £82. 15s. cash, and £80. to £80. 5s. three months. Tin: G.M. quality, £174. 10s. to £175. cash, and £174. 5s. to £174. 15s. three months; English, £178. Lead: soft foreign, August delivery, £19. 12s. 6d.; September, £19. 10s.; October, £19. 5s. to £19. 7s. 6d.; November, £19. 2s. 6d.; English, £20. Spelter: ordinary brands, September shipment, £22. to £22. 5s. ex ship; hard, £18. 10s. to £19., f.o.b. Antimony, £40. to £43.; ore, £9. to £10. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 16s. Nickel, £175. to £185. Pig-iron: Closing prices: Cleveland, 57s. 8½d. cash, and 57s. 8d. one month.

MISCELLANEOUS CHEMICAL MARKET.

THURSDAY.

Upon the whole business is steady, though a rather quieter tone is noticeable in some branches of the chemical trade, which is not unusual at this season. In the principal products of the alkali trade there are no changes in values of material importance. Sulphate of copper is lower, at £30. 10s. to £30. 15s., in sympathy with the lower price of copper. Alkali, 58%, is firm, and in steady good demand at £4. 10s. per ton, bags, f.o.r. Soda crystals 60s. per ton. Bleaching powder for delivery this year £4. 7s. 6d. to £4. 10s., f.o.r. Chlorates unchanged at 3½d., usual conditions. Caustic soda, 70%, stands at £9. 15s., f.o.b., and other strengths at the usual relative prices. Saltcake, in bulk, is in good general request both for home and export, at 40s. to 42s. 6d. per ton, f.o.r. and f.o.b. Sulphur is steady at £4. 17s. 6d. per ton, f.o.r. Acetate of lime, 80%, firm at £12. 10s., c.i.f. Acetate of soda, £16. 15s. to £17., c.i.f. Sugar of lead, all qualities, quiet, but prices without further change. Acetic acid keeps steady at former quotations. Ammonia and ammonia salts continue in good general request, and quotations are firm. Prussiates meet with better inquiry.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—The effect of the holidays upon this market has been weakening, more so in regard to linseed than cottonseed oil. The position of linseed oil is not strong, and value is only maintained with difficulty by the crushers. Amongst the principal imports here to date, as against the same time a year ago, are:—Wheat 2,418,906 qrs., against 2,367,011 qrs.; flour, 114,432 cwts., against 227,913 cwts.; linseed 424,518 qrs., against 311,739 qrs.; rapeseed 50,684 qrs., against 44,251 qrs. Cottonseed, Egyptian, 122,221 tons, against 105,741 tons; other kinds, 105,747 tons, against 91,718 tons; oilcake 17,437 tons, against 25,489 tons; hemp 81,315 cwt., against 106,572 cwts.; olive oil 3,379 tuns, against 2,857 tuns; tar 2,344 brls., against 3,725 brls. Amongst the weekly imports: Lard 1,121 cwts., sugar 15,005 cwts., hides 454 cwts., colours 299 pkgs., wool 33,890 lbs. Exports: Oil 9,496 cwts., colours 3,149 pkgs., Linseed oil closes quiet, at 22s. 6d., naked; August, 22s. 3d.; September-December, 21s. 1½d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports for the week: 1 ton Austria, 3 Denmark, 7 France, 12 Germany, 5 Norway; total, 28 tons. Linseed is generally quieter: La Plata, 40s. 6d.; July-August, 41s.; Calcutta, July-August, 42s. 6d. Refined cotton oil steady, spot and month 28s. 9d.; September-October, 27s. 10½d.; November-April, 23s. 9d.; casks £1., and barrels £1. 10s. per ton extra. Exports for week have been:—3 tons Denmark, 4 France, 41 Germany, 22 Holland, 1 Norway, 4 Sweden; total, 75 tons. Cottonseed: But little business passing; spot, £8. 3s. 9d.; afloat, £8. 3s. 9d.; August, £8. 5s.; October, £7. 5s.; November-January, £7. 2s. 6d. to £8. 3s. 9d.; Bombay, July-August, £5. 15s. 3d. Rapeseed quiet. Turpentine quiet: American, 42s. September-December, 43s.; January-April, 44s. 3d.; Russian easier, 21s. Rosins quiet, 11s. upwards. Olive oil, £41. to £42. per tun. Castor oil, November-December, 30s. 6d.; January-June, 30s. 9d. for first pressure.

CAKES.—A generally steady market for feeding stuffs, with linseed cakes firm. Cotton cakes rather scarce; prices steady. Bombay cakes rather quiet and not so much in demand.

PAINTS.—Quiet for export. Home market prices unchanged.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

Palm oil steady, sales including Lagos, on spot, £30. 10s. per ton. Olive oil quiet, and without change. Linseed oil steady, at 25s. 9d. to 26s. 6d., for Liverpool makes in export casks. Cottonseed oil in moderate inquiry, at 31s. 6d. to 32s. per cwt., for Liverpool refined, in export barrels. Rosin steadily held. Tallow quiet, at 32s. to 34s. 6d. for Norths; and Matadero mutton, 35s. per cwt., c.i.f. Turpentine steady, at 42s. per cwt., on spot. Petroleum firm, at 6½d. for Russian and Roumanian; and 7d. to 8d. for American refined oils. Petroleum spirit steady, at 1s. 0½d. to 1s. 3d. per gallon, on spot.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

Digitized by Google

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes quiet. Pearl ash nominal. Bark steady. Logwood and fustic steady, with nominal supplies. Cutch quiet. Gum arabic steadily held. Castor oil steady, at 3 5/16d. for good seconds Calcutta; 3 7/16d. to 3¼d. for first pressure French; and 3½d. for second pressure French; Calcutta, well held at 3¼d. for August-September shipment. Gambier quiet, at 19s. to 19s. 6d. for block, on spot, and 18s. for June-July and July-August shipment; cubes in limited supply, at 28s. 6d., on spot, and 27s. 9d. for August-September shipment. Shellac quiet, at 205s. for spot TN orange. American powdered starch, 10s. on spot, and 9s. 6d. c.i.f., for shipment; pearl, 9s. 4½d. on spot, and 9s. c.i.f., for shipment. Cream of tartar, 98% foreign powder, 81s.; 95%, 79s. Tartaric acid: English, on spot, 11¼d.; and foreign, 11d. Citric acid, English, 1s. 11½d.; foreign, 1s. 11d.

TYNE CHEMICAL REPORT.

THURSDAY.

Chemicals continue in quiet demand, with a steady business doing, and no change in prices.

Caustic soda, 70%, £9. 15s.; and 76-77%, £10. 10s. per ton. Soda crystals, locally, £3. to £3 2s. 6d. per ton gross weights. Bleaching powder, £5. to £5. 5s. per ton. Sulphur firm, at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2-cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett, do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5-7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (salt cake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market is very firm, and all coals are very strongly held. The long loading turns are making business difficult, and very little coal is obtainable for August. Everything points to a firm market for some little time, and this will be accentuated by the fact that the Durham miners have just been awarded an advance of 7½% in wages. Current quotations:—Best Northumbrian steam, 16s. to 16s. 3d. per ton; second qualities, 15s. 6d. to 15s. 9d. per ton; small steam, 10s. to 10s. 6d. per ton; best gas coals, 15s. to 15s. 6d. per ton; good Durham bunker, 13s. 3d. to 13s. 9d.; coking coals, 14s.; household coals, 10s. to 17s. per ton; foundry coke, 25s. per ton; gas coke, 20s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

In the ordinary heavy chemicals during the past week there has been some little tendency in the direction of increased movement, and values are correspondingly firmer, though without any specific change. The somewhat brisker demand applies to both spot and forward, and in the case of the latter the feeling is towards some advance, in view of the higher costs of fuel, labour, etc. Sulphate of ammonia, Leith and Glasgow deliveries, remains unwontedly steady in quotations, (no change of any consequence for some weeks), although there is little of activity in actual dealing, and what little there is, confined to spot business. Nitrate of soda also continues quiet and with little or no variation in value. Sulphate of copper maintains the recent slowly lowering tendency, the figure to-day being about £30. 5s.

Chief prices current are:—Alum (in lump) £5. 5s. to £6. nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s. nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b., Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b., Glasgow); bleaching powder, 35-37%, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16.; and boracic acid, £25., nett, Glasgow; caustic soda, white, 76%, £10. 10s.; 70-72%, £9. 15s.; 60-62%, £8. 15s.; and cream, 60-62%, £8. 15s., all nett, Liverpool; chlorate of potash, 3½d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace) 2¼d., naked, f.a.s., Glasgow; nitrate of soda, 11s. 3d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 1⅞d. to 2¼d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¾d.; ordinary sorts, 6¼d. and 6½d., new season's contract prices at Glasgow and other big centres; ditto (lubricating) 805°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; and 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42. and £40., less 2½% any port; saltcake, 40s. to 42s. 6d.; soda ash, £5. 10s. to £5. 15s. nett Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d. prompt, f.o.b. Leith; sulphate of copper, £30. 5s., less 5% Liverpool, prompt.

New Companies.

Biological Sewage Disposal (Dibdin's System), Ltd.—Capital, £13,000., in £1. shares. This company has been formed to acquire from W. J. Dibdin the benefit of a certain existing invention relating to improvements in sedimentation tanks or the like, particularly for sewage treatment, and to develop and turn to account the same. Minimum cash subscription, 25% of the shares offered to the public. The first directors are W. J. Dibdin, H. J. Hadrill, W. C. Dickinson, and G. Stevenson. Qualification (except first directors) £250. Remuneration, £150. each per annum (chairman £200.) and 5% of the net profits, divided. No remuneration for W. J. Dibdin in any year unless 5% dividend is paid on the ordinary shares. Registered office, 15, Leadenhall-street, E.C.

Cail's Bitmo Co., Ltd.—Capital, £30,000., in £1. shares (6,000 preference). This company has been formed to acquire the business of manufacturers of and dealers in bituminous preparations and compositions and heat proof cements, carried on by W. Cail, J. Harbottle and T. Pemberton, trading as William Cail and Partners, and by Holzapfel's Compositions Co., Ltd., at Newcastle-on-Tyne and elsewhere. No initial public issue. The first directors are W. Cail (managing director), J. Harbottle and A. C. A. Holzapfel (of 57, Fenchurch-street, E.C.). The directors of Holzapfel's Composition Co., Ld., may, during the first seven years' nominate one director, the said A. C. A. Holzapfel being their first nominees. After the first seven years, any holder of 7,500 shares may nominate one director. Registered office, 3-4, Cail's Buildings, Quayside, Newcastle-on-Tyne.

Cleveland Magnesite and Refractory Co., Ltd.—Capital £10,000., in £1. shares. This company has been formed to carry on the business of manufacturers of and dealers in fire-resisting goods, including ganister, silica, magnesite and chrome bricks, ground ganister, etc. No initial public issue. The first directors are H. N. and F. H. Brooke, T. Twynam and J. B. Peat; qualification £200.

Norse Zinc Co., Ltd.—Capital, £250,000., in £1. shares. This company has been formed to acquire certain mining claims and rights over lands in Norway, and to adopt an agreement with the Contract and Securities Co., Ltd. No initial public issue. The first directors are to be appointed by the subscribers; qualification 1 share; remuneration £100. each per annum and £50. extra for the chairman. Registered office, 19, Basinghall-street, E.C.

Oowana Soap and Candle Co., Ltd.—Capital £60,000., in £1. shares. This company has been formed to adopt agreements (1) with B. P. Maisel and (2) with Oowana, Ltd., and to carry on the business of soap and candle manufacturers and merchants, etc. Minimum cash subscription 10% of the shares offered to the public. The first directors are H. G. Smith (chairman), J. A. Cooney, F. O'Shaughnessey B. Reade, Rear-Admiral C. Windham and B. P. Maisel; qualification £100.; remuneration not less than £50. each per annum. Registered office, 26, Red Lion-square, W.C.

Siputeh Tin Mines Ltd.—Capital, £40,000., in £1. shares. This company has been formed to adopt an agreement with F. E. Mair, and to carry on in the Federated Malay States and the Straits Settlements, the business of miners, explorers, prospectors,

Digitized by Google

metallurgists, smelters and preparers for market of metals, ores and minerals, etc. No initial public issue. The subscribers are to appoint the first first directors; qualification 250 shares; remuneration (except managing director) £150. each per annum (chairman £200.) and 5% of the net profits after providing for 15% of the shares, divided.

Stern Sonneborn Oil Co., Ltd.—Capital £25,000., in £5. shares (2,000 6% cumulative preference). This company has been formed to acquire (1) that part of the business of the Oelwerke Stern Sonneborn Aktien Gesellschaft of Hamburg, Cologne and Paris, which is carried on in the United Kingdom and the Colonies, Dependencies and Protectorates of the British Crown under the sole agency of ,and in part in joint account with J. Wallach and L. C. Wallach (trading as Wallach Brothers) under the style of the Stern Sonneborn Oil Co.; and (2) the business of the Chemische Werke für Textil Industrie G. M. B. H., of Hamburg, carried on in the British Empire, to adopt agreements (1) between the Oelwerke Stern-Sonneborn Aktien Gesellschaft of the 1st part, J. Wallach and L. C. Wallach of the 2nd part, and this company of the 3rd part; (2) with the said J. Wallach and L. C. Wallach, and (3) between the Chemische Werke fur Textil Industrie and Wallach Brothers, of the 1st part, the said J. Wallach and L. C. Wallach of the 2nd part, and this company of the 3rd part, and to carry on the business of manufacturers, importers, exporters, refiners and blenders of and dealers in oils, greases, lubricants, petroleum jelly, etc. No initial public issue. The first directors are L. Stern, J. Sonneborn, J. Wallach and L. C. Wallach; qualification, £100. shares or stock. J. Wallach and L. C. Wallach are managing directors, with remuneration as fixed by the board or by the company.

Week ending July 27.

AMENDMENT.

C.T.J., No. 1051, p. 108, Aug. 3.—**Bleaching Powder**, France, £244, ditto £286, ditto 301 t., U.S.A., 2,633 t., *should read* **Phosphate of Lime.**

Acetic Acid—
Holland, 25 cs. W. H. Muller
,, 10 pks. & Co.
,, 22 R. W. Greeff
,, 4 cks. & Co.
Norway, 31 B. Biggs & Co.
,, 75 crbys. Weber, Smith & Hoare
Germany, 17 H. W. Brummerstaedt & Co.

Acetone—
France, £170 H. W. Champney
A. Hung., 807 S. F. Griffiths

Alum—
Belgium, 4 cks. J. W. Steel & Co.

Aluminium—
France, 1 t. O. Murray & Co.

Aluminium Sulphate—
Holland, £200 Ohlenschlager Bros.

Ammonium Muriate—
Holland, £130 A. & M. Zimmermann

Antimony (Regulus)—
N.S.W., 4 t. Leach & Co.

Antimony (Crude)—
Germany, 23 t. Quirk, Barton & Co.

Antimony Ore—
N. Zealand, 6 t. Union Ltge. Co.

Argols—
Spain, 562 brls. J. B. Jacob & Sons
,, 45 cks. Thames S. T. & L. Co.
Italy, 437 bgs. J. B. Jacobs & Sons

Arsenic—
Spain, £330 Charles & Fox

Asbestos—
U.S.A., 2 t. 5 c. Deering & Robottom

Barytes—
Belgium, 231 cks. Felton & Crepin
,, 300 bgs. Crepin
,, 52 cks. Perkins & Homer
,, 72 Taylor Bros.
,, 71 W. Harrison & Co.
,, 22 Petri Bros.

Barytes—
Holland, 46 cks. O'Hara & Hoare
,, 43 100 bgs. W. Harrison & Co.
,, 158 520 Felton & Crepin
,, 68 J. Greig
,, 80 Phillipps & Graves
,, 24 O Lechla
Germany, 664 G.G. France's
,, 40 Taylor Bros
,, 360 Luke & Bailey

Barium Peroxide—
Germany, £38 London & Rhine S. Office

Basic Slag—
Belgium, 380 t. Anglo Cont. Guano Wks.
France, 2 Bennett's S.S. Co.

Bleaching Powder—
Holland, 14 W H Muller & Co.

Bismuth—
Germany, 3 t Argo S S Co.

Bismuth Carbonate—
Germany, £76 T H Lee

Bog Ore—
Holland, 478 t. W. Hawkins & Co.
Belgium, 250 J. Harrison & Co.

Bones—
Argentine R, 14 t. J. Nelson & Son

Borax—
Germany, 1 t. 10 c. A. & M. Zimmermann

Calcium Carbide—
France, 52 t. J. Harrison & Co.

Camphor—
Japan, 10 cs. H. Irven & Co.
U.S.A., 30 Stallman & Fulten
France, 50 S. Figgis & Co.
Germany, 1 ck. Prop. Hay's Wf.

Caoutchouc—
France, 3 c. L. & I. D. Jt. Co.
,, £11 Weber, Smith & Hoare
,, 4 Shaw, Adams & Co.
Aden, 12 L. & I. D. Jt. Co
,, 18 Clarke & Smith

Caoutchouc—
Germany, 6 c. France, Fenwick & Co.
,, 1 t. 4 Props. Bull Wf.
,, 2 11 Clarke & Smith
,, 1 L. & I. D. Jt. Co.
,, 7 Prop. Hay's Wf.
Burmah, 16 2 L. & I. D. Jt. Co.
,, 2 1 S. Figgis & Co.
,, 5 Prop. Hay's Wf.
,, 1 Lyall, Anderson
,, 3 L. & I. D. Jt. Co.
Straits, 4 20 Prop. Hays Wf. L'd.
,, 5 Jewesbury & Co.
,, 3 Props. Bull Wf.
,, 2 7 L. & I. D. Jt. Co.
Ceylon, 7 Hoare, Wilson & Co.
,, 2 L. & I. D. Jt. Co.
,, 9 Leach & Co.
,, 10 Lewis & Peat
,, 1 Crabbe & Co.
,, 3 Props Bull Wf.
E. Indies, 18 W. H. Smith
,, 15 Lewis & Peat
,, 2 5 Props. Bull Wf.
Aden, 2 Baxter, Hoare & Co.
,, 4 Props. Bull Wf.
Natal, 3 L. & I. D. Jt. Co.
U.S.A., 6 5 Props. Bull Wf.

Carbon Tetrachloride—
Germany, £35 Fuerst Bros.

Castor Oil—
France, 15 cs. Litchfield & Soundy
,, 15 bls. Weber, Smith & Hoare
Belgium, 48 brls. Fuerst Bros.
,, 1 cs. ,,
E. Indies, 88 cks. Layzer, Irvine & Co.
France, 15brl. 40 F. Boehm
Italy, 30 ,,

Castor Oil—
France, 10 brls. Mordaunt Bros.
,, 25cs. R. Warner & Co.
,, 12 Litchfield & Soundy
Italy, 25 ,,
France, 5 cks. 5 L. & I. D. Jt. Co.

Caustic Potash—
France, 28 dms. J. Barber & Co.
Germany, 36 R. Waters

Chalk (French)—
France, £21 J. Harrison & Co.
,, 82 Atkins & Nisbet

Chemicals (*otherwise undescribed*)
Holland, £160 W. H. Muller & Co.
,, 6 A. & M. Zimmermann
,, 80 B. & F. Wf. Co.
,, 1 890 L. A. Smith
Belgium, 95 Reitmayer & Co.
,, 14 Leach & Co.
,, 5 D. C. Thomas & Sons
,, 9 J. Harrison
,, 12 J. Cockerill Line
,, 7 J. Harrison
Germany, 138 T. H. Lee
,, 269 A. & M. Zimmermann
,, 58 Argo S.S. Co.
,, 30 L. & I. D. Jt. Co.
,, 10 E. J. Brash
France, 100 W. Smith
,, 27 J. Barber
,, 15 H. Johnson, Sons & Co.
,, 12 J. Harrison
,, 13 G.T. Symons & Co
Norway, 210 W. Smith
U.S.A., 400 B. & F. Wf. Co.
Germany, 7 c. D. C. Thomas & Sons

Cinchona Bark—
E. Indies, 59 bls. Beresford & Co.
,, 97 Hoare, Wilson & Co.
,, 99 Weber, Smith & Hoare
Ceylon, 9 brls. M. P. Evans & Co
Holland, 325 J. W. Cook & Co.

Chromium—
Holland, 6 cs. J. Barker & Co.

Citric Acid—
Holland, 2 cks. Kirkpatrick, Barr & Co.

Coal Products—
Carbolic Acid
Holland, 50 cks. J. Owen
Holland, 100 Hollinghurst & Co

Digitized by Google

Coal Products—

Aniline		
Germany,	16 pks.	L. & I. D. Jt. Co.
Belgium,	2 cks 2 cs.	Leach & Co.
,,	35 pks.	J. Cockerill Line
Pitch		
N. Russia,	400 brls.	London Oil Stge. Co.

,,	91	France, Fenwick & Co.
U.S.A.,	3 kgs.	Simpson, Spence & Co.
Ceylon,	4 brls.	L. & I. D. Jt. Co.

Potassium Carbonate—

Germany,	19 cks.	Petri Bros.
,,	18	F. Fink & Co.
,,	4	Charles & Fox
Belgium,	10 brls.	Beresford & Co.
U.S.A.,		
Canada,	10	Charles & Fox

Potassium Chlorate—

France,	215 cks.	C. Murray & Co.
Sweden,	25 kgs.	G. Boor & Co.

Potassium Iodide—

Japan,	£497	L. & I. D. Jt. Co.

Potassium Metasulphite—

Germany,	£42	A. & M. Zimmermann

Potassium Permanganate—

Germany,	42 kgs.	L. & I. D. Jt. Co.

Potassium Prussiate—

Belgium,	4 cks.	J. Owen

Quinine—

Holland,	26,000 ozs.	J. Barber & Co.

Red Lead—

Germany,	18 cks.	Randall Bros.
Belgium,	41	C.S. Lovell & Sons
France,	40 brls.	J. Watt & Son

Ripolin—

Holland,	10 cts. 27 cs.	Phillipps
,,	11 dms.	& Graves

Rosin—

Germany,	17 bls.	London & Rhine S. Office
France,	50 brls.	G. S. N. Co.
,,	3	B. & F. Wf. Co.

Salicylic Acid—

Germany,	5 cs.	T. H. Lee

Saltpetre—

Germany,	60 t. 10 c.	P. Hecker & Co.
,,	10	L. & I. D. Jt. Co.

Silver Concentrates—

N.Z.,	£1,620	H. J. Enthoven & Sons

Silver Nitrate—

Germany,	£378	T. H. Lee

Silver Ore—

U.S.A.,	7 t.	B. Ackerley & Son

Soap—

N.S.W.,	£75	Lucas & Spencer's Wf.
France,	23	Mory & Co.
,,	33	Beresford & Co.
,,	460	Lucas & Spencer's Wf.

LATE ADVERTISEMENTS.

THE GLASGOW & WEST OF SCOTLAND TECHNICAL COLLEGE, GLASGOW.

Departments of Chemistry, Technical Chemistry, and Metallurgy:—

Chemistry: Professor G. G. Henderson, M.A., D.Sc., F.I.C.
Technical Chemistry: Professor Thomas Gray, D.Sc., Ph.D.
Metallurgy: Professor A. Humbold Sexton, F.C.S., F.I.C.

The Courses of Instruction in these Departments are arranged for Students preparing to become Manufacturing or Analytical Chemists, Metallurgists, or Science Teachers. The Courses in Chemistry qualify for the examinations of the Institute of Chemistry, and of the Universities of Glasgow, Edinburgh, and London. Session 1907-1908 begins on Monday, September 23rd, in the new buildings recently erected for the College. The Entrance Examination begins on Monday, September 16th. Calendar (by post 1/1) containing regulations for the Associateship of the College and prospectus (gratis) may be obtained from the Secretary.

CHEMICAL Plumber seeks situation.—"1468." *Chemical Trade Journal* Office, 265, Strand, London, W.C.

CHEMIST wanted, thoroughly acquainted with the manufacture of Sulphur Black, etc. Apply, stating wage and experience.—"1469," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

AN old-established Business of Manufacturing Chemists and Merchants with a large connection, to be sold as a going concern. Full particulars from Thomson, Hill & Co., Chartered Accountants, 43, Cannon Street, E.C.

ENGINEER wanted for India to take charge small Fish Manure and Oil Plant; state age and experience, salary required. &c.—H. & Co., 127, Fenchurch Street, London, E.C.

MANURE Trade (wholesale).—Wanted, experienced Representative to manage business in India; must be good buyer, accustomed to shipping and finance; state experience, salary required, &c.—H. & Co., 127, Fenchurch Street, London, E.C.

GENERAL Manager of large and up-to-date Manure and Chemical Works, possessing a thoroughly practical knowledge of every branch of these and the allied trades, also a fine English and shipping connection, is desirous of joining a firm of first-class standing, one who can utilize a connection in Manures, Dips and Disinfectant, exceeding £100,000 per annum. Highest references and good generous terms offered for a rapid change.—Apply in first instance, D.Sc. (Lond.), 382, Sell's Advertising Offices, London, E.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

CURRENT TOPICS.

THE JULY TRADE RETURNS.

THE Board of Trade returns for July show conclusively that the "boom" in our overseas commerce is by no means at an end. The imports during last month are valued at over three and a half millions sterling more than during the corresponding month of 1906, while in exports the increase is no less than seven millions. The comparison with 1905 is even more striking, the gains being seven and a half millions and twelve and a half millions respectively. The totals for the first seven months of this year are also record figures. Our imports to the end of July are thirty-one millions greater than in 1906, and sixty-two millions greater than in 1905. Exports are up by thirty-two millions as compared with 1906, and by the phenomenal figure of sixty-three millions over the previous year. As regards chemicals, the July imports and exports both show substantial increases, while the advances for the seven months are £910,834. and £1,190,706. respectively. Our usual monthly analysis is given below.

The returns for July show an increase of £3,605,505. in the value of total imports, and an increase of £7,009,369. in total exports, as compared with July, 1906. Total imports (value c.i.f.) were £52,213,304., against £48,607,799.; total exports of British and Irish produce (value f.o.b.), £40,452,331., against £33,442,962. The comparison with 1905 shows an increase of £7,471,269. in imports, and an increase of £12,631,280. in exports.

The imports of chemicals, drugs, dyes, and colours in July amounted to £972,815., against £843,383. in 1906, an increase of £129,432. The imports of bleaching materials in July were valued at £3,741., against £5,153., and of soda compounds £14,275., against £7,697. in 1906.

The exports of chemicals, drugs, dyes, and colours in July amounted to £1,363,942., against £1,193,376. in 1906, an increase of £170,566. During the month the principal items were:—Bleaching materials, 75,832 cwts., valued at £16,347., against 87,230 cwts. and £18,315. in 1906. Coal products (not dyes), value £102,777., against £85,123. in 1906. Copper sulphate, 1,245 tons, valued at £39,027., against 1,426 tons and £34,425. in 1906. Dyestuffs, £34,427., against £21,922. in 1906. Glycerine, £39,190., against £23,680. in 1906. Chemical manure, 50,978 tons, valued at £309,766., against 49,696 tons and £259,535. Muriate of ammonia, 13,917 cwts., valued at £17,778., against 9,668 cwts. and £12,570. in 1906. Painters' colours and materials, 177,618 cwts., valued at £225,871., against 182,914 cwts. and £227,364. in 1906. Soda compounds, 506,107 cwts., valued at £160,313., against 422,881 cwts. and £122,264. in 1906. The exports of salt in July amounted to 70,786 tons, valued at £57,435., against 60,965 tons and £42,779. in 1906. Exports of "unenumer-

Digitized by Google

ated chemicals" were valued at £253,308., compared with £247,668. in 1906.

The imports of oil seeds, nuts, oils, fats, and gums in July amounted in value to £3,062,601., against £2,221,426. in 1906, an increase of £841,175. The figures for petroleum were 29,842,182 gallons, valued at £631,443., against 22,593,394 gallons and £473,812 in 1906. The value of exports of oil seeds, nuts, oils, fats, and gums was £273,997., against £247,035., an increase of £26,962.

The imports of metals and minerals during July were :— Copper ore, 10,634 tons, valued at £161,942., against 7,732 tons and £86,927. in 1906. Copper (regulus and precipitate), 7,614 tons, valued at £374,614., against 5,786 tons and £205,528. in 1906. Lead (pig and sheet), 18,402 tons, valued at £366,376., against 20,067 tons and £326,643. in 1906. Pyrites of iron and copper, 49,207 tons, valued at £77,189., against 65,567 tons and £110,256. in 1906. Quicksilver, 41,400 lbs., valued at £3,613., against 824,930 lbs., valued at £79,015. in 1906. Silver ore, value £156,509., against £194,204. in 1906. Tin, 3,924 tons, valued at £737,341., against 3,268 tons and £552,238. Zinc (crude), 7,880 tons, valued at £202,805., against 8,222 tons and £209,828.

THE BRITISH ASSOCIATION, THE "TIMES," AND SENSATIONALISM IN SCIENCE.

In our last issue we reproduced the first part of Professor Smithell's highly interesting presidential address before the Chemical Section of the British Association, and elsewhere in this number the completion of the address appears.

Professor Smithells protested against the prevailing tendency among men of science to indulge rather too freely in the pursuit of theory, and in its presentation in language more sensational than is warranted by ascertained facts. In a very pertinent editorial comment on this address, the *Times* drives home the warning in the following passage : "With regard to his own science, Professor Smithells insisted that the important thing is training in the art of exact experiment, not training in the abstruse branches of mathematics which offer results far outrunning exact demonstration. There is never, he observed, greater cause for anxiety than when we see a mathematical theory awaiting the delivery of the confirmatory facts. We may notice a good deal of such theory at the present day, and we may also perceive illustrations of its danger in the feverish haste with which some investigators spring upon the world alleged discoveries confirmatory of theory, but founded upon no experiment that would otherwise be held to merit attention. This is bad in science and bad in morals. It is entirely contrary to the spirit in which science has won all her real triumphs ; and it betrays a desire to snatch unmerited laurels by launching mere guesses, upon the chance that, when someone else arrives at a conclusion by hard work, the guesser may put forth a claim to priority. If no verification of the guess ever appears, kindly oblivion is trusted to for the covering up of the guesser's folly. In the meantime he has had his little sensation in the more irresponsible portion of the Press, where somebody has probably declared him the greatest something-or-other of all time. Hard work is discouraged and discountenanced by these proceedings, and science itself is brought into disrepute. It is impossible to estimate the extent to which such conduct destroys the force of the appeals made to unwilling ears for greater encouragement of science by the State. Those who have no interest in science, whether genuine or spurious, are always ready to point to the spurious as a reason for shutting their eyes harder than ever to the claims of the genuine. Science cannot play with sensationalism without paying the penalty. Though all men of science do not yield to the fashion of the time, it is certainly not condemned with sufficient rigour, and the Royal Society itself is far from exercising as it ought its regulative and disciplinary functions."

There is no doubt that this somewhat merciless castigation of the sensationalist in science is merited, but the *Times* does not stop here. It points out that Sir David Gill, in his address as President of the British Association, though not so outspoken as Professor Smithells, inculcated the same lesson when he pointed out that the very best thing an astronomer can do to-day is hard and patient work in determining measurements with the highest degree of exactitude. Comprehensive theories of the origin of the universe are more fascinating and make more talk, but they are merely laborious conjectures at the best, and sometimes they are not so much as that. So in chemistry there are scores of problems lying unsolved, the true solution of which will be reached, if at all, by unlimited patience in carrying out exact measurements and careful observations, not by spinning theories to explain the constitution and origin of matter.

Passing on to radium as an example of scientific sensationalism, the *Times* belabours the reckless theorist in measured terms. "There are plenty of lucubrations at the present day which are merely metaphysics, and not good metaphysics. Except that terms are altered, they are identical with the medieval speculations upon which we are expected to look down from the superior heights of exact knowledge. Take the enormous mass of airy conjecture that has been built up about radium. Professor Smithells seems to concede too much when he says that it would be conventionally called an element. An element is something that we cannot decompose into anything simpler ; but radium, we are told, is always decomposing into all sorts of things. But whatever it may be called conventionally, how much is really known about it in the way that chemists understand knowledge of a substance ? It has never been isolated. It has never been dealt with except in very minute quantities of some compound of some unknown thing which may or may not be analogous to the metals which its question-begging name suggests. Different people have got the most amazing spectroscopic results, but by processes which are open to the introduction of the most amazing uncertainties. If ever there was a substance about which it behoves us to speak with diffidence it is radium. Yet the speculations to which it has given rise revolutionise the whole science of chemistry, if they are true. Professor Smithells refuses to regard his science as revolutionised, but that is only a polite way of saying that he does not believe the speculations. Indeed, he remarks that spectroscopy, dealing with substances of which we do not possess enough to test conclusions in the ordinary way, seems to be creating a 'chemistry of phantoms.' These are taken up by the mathematicians, who prove to their own satisfaction that, in conditions defined by themselves, things might happen in a given way, and thence conclude that, in conditions far beyond their ken, things do happen in that way. Radium and everything else is thus reduced to electricity, and the world is supposed to have made a vast stride in knowledge, although nobody has a ghost of an idea what electricity is, and the theorists themselves cannot fit positive electricity, whatever that may be, into

Digitized by Google

their scheme. This is medieval metaphysics masquerading in the garb of exact science, and it is not even good metaphysics, because words are continually employed in different senses in the same argument."

No genuine scientist will quarrel with the *Times* for this outspoken protest, but we quite agree with our pharmaceutical contemporary, the *Chemist and Druggist*, in its summing up of this discussion of scientific sensationalism. Our contemporary says:—"We are not sorry to see this plain speaking, whomsoever it may be aimed at, for the elementary attributes of radium are matters of deduction; but if the *Times* means to discourage the research along new lines, we are not with it. The radium research has not so far displaced a single principle of chemistry, but it has made advances which have helped to open the minds of the hide-bound to the fact that man-made laws are not finality."

NEW COMPANIES IN 1907.

The registrations of new companies at Somerset House during the first half of 1907 were greater than in any corresponding period in the last nine years. In the six months under review, 2,479 companies, having a total nominal capitalisation of £73,994,832. were registered, as compared with 2,255 companies and £64,153,340. in the first half of 1906. In his last annual report, the Comptroller of the Companies Department of the Board of Trade comments on the tendency to decrease in the average nominal capital of new companies, and in a half-yearly review in the current number of the *Investor's Guardian* this point is also emphasised. Ten years ago the average capitalisation was £56,700.; last year it was £28,500., and during the past six months it has been £29,900., the increase being due particularly to two large registrations, accounting for £7,000,000. of capital—the Royal Insurance Company, re-registered under the limited liability laws, with a capital of £3,000,000., and the Anglo-Saxon Petroleum Company, with £4,000,000. Four other companies were registered with a capital of £1,000,000. and over. The half-year, indeed, has been fairly prolific in these extra large registrations, there being three companies with £1,000,000. each—the general Investors and Trustees, the Merton Metallurgical Company, and the Vanguard Motor 'Bus Company—and one with £2,000.000.—the British Coalite Co. These six companies give a nominal capital of £12,000,000. against four "million" companies with a total capital of £5,000,000. in the first half of 1906.

Our financial contemporary continues:—"The increase in the number of this largest class of registrations may be taken as in itself an indication of an improved outlook in the joint-stock world. The six 'million' registrations of the past six months compare with eight during the whole of 1906, six during 1905, five during 1904, and 11 during 1903, whereas in the 'fever years' of the late 'Nineties there were registered: in 1897, 30 companies of £1,000,000. capital and over; in 1898, 29; and in 1899, 31. It may be added, by way of contrast, that in 1906 there were registered 1,742 companies with a capital of £5,000. and under, against 1,005 in 1897; these figures, in conjunction with those of the companies of £1,000,000. and over, emphasising the greater use of the joint-stock system for private business purposes, and the continued inertness of the speculative market."

An analysis of the general body of new companies shows that the engineering and allied groups do not exhibit great developments. The coal and fuel section is swollen by the £2,000,000. "Coalite" registration; engineering and hardware trades show healthy activity; and textile registrations continue well supported. The "chemical and medical" class—surely a very loose classification of an important section—shows an increase from £1,115,335. in the first six months of 1906 to £1,193,207. in the corresponding period of 1907; this latter figure, however, compares with £1,758,293. in 1905. The oil section shows a big jump, owing chiefly to the 4-million registration of the Anglo-Saxon Petroleum Company. Rubber continues to attract joint-stock enterprise, accounting in the past half-year for £1,850,000. of new registrations, against £2,600,000. in the first half and £1,900,000. in the second half of last year.

Scottish registrations show an increase of two in numbers and of £533,000. in capital aggregate. The strongest groups are insurance and engineering. Ireland, with two registrations less, shows an increase of £280,000. in capital, a large Belfast company accounting for this.

Guernsey registrations have ceased to have any practical importance. Only 11 companies were registered there during the half-year, and four of these were local. The seven English companies have a total nominal capital of £749,500. The assimilation of the company laws of the Channel Islands to those of the rest of the United Kingdom is under the consideration of the Law Officers.

COMPANY LAW IN THE BRITISH EMPIRE.

Mr. George Stapylton Barnes, Comptroller of the Companies Department of the Board of Trade, in an analysis of the company laws of the United Kingdom, India, Canada and other colonies—published recently as a Blue Book—states that, with regard to the suggestion of a unified code for the whole Empire, such a code would be impossible owing to the varying needs of each part of the Empire. A greater measure of simplicity and uniformity might, however, exist than is at present the case.

The trend of recent legislation had been to afford as much information as possible concerning joint-stock companies, on the ground that publicity was the best protection for creditors and investors. Legislation could not endow people with prudence or business habits, but it could give the creditor and investor the necessary information to enable him to form a judgment. The Bill at present before Parliament would carry this principle still further by giving more complete information as to the outstanding mortgages and charges, and by imposing a duty on prospectusless companies to file a statement, in place of a prospectus, which statement should contain the same material information.

Uniformity would be commercially of the greatest use in furthering such facilities. The same information might easily be made accessible, no matter whether the company was registered in the United Kingdom or anywhere else in the Empire. At present there was too much divergence of law and practice in this respect. Now that so much trade was done by joint-stock companies, an assimilation of the law of companies would be of the greatest benefit to the mercantile community; it would also strengthen the confidence of the home investor in companies registered abroad, and would thus increase the flow of home capital into Indian and Colonial enterprises.

MATHER AND PLATT, LTD.—The directors have declared an interim dividend on the ordinary shares of 3%, being at the rate of 6% per annum, free of income tax, for the half-year to June 30.

DUTCH MADDER.

MESSRS. W. BUNGE & CO., of Rotterdam, report as follows, under date August 1 :—

A quiet market has prevailed during the last month, with little of interest to report. Supplies remain light, and seem to be sufficient for the present demand. Prices are rather lower, and will not fail to attract more attention shortly. Present quotations, per cwt., in original butts, actual tare, free on board Rotterdam, are as under :—

Fine crop	55/-
Small crop	49/- to 51/-
Fine Ombros	42/6 „ 48/-
Good „	39/- „ 41/6
Small „	39/- „ 41/6
Regrounds	44/-
Mulls	7/- „ 11/-
Roots	— —
Garancine	50/- „ 75/-

THE INDIGO MARKET.

MESSRS. MILLWARD & CO. report as follows, under date August 12 :—

Since the July sales there has been a steady business at firm prices. The principal inquiry is for medium Bengal testing about 60%, which description is, however, scarce and relatively dear at present, better value being obtainable in the finer qualities. There is not much general demand for indigo, either for cotton or wool, but some large users have got to the end of their stocks, and are cautiously operating. Inquiries for export are much more numerous than orders, but there are indications that larger business will soon be booked. Reports from Calcutta concerning the new crop are far from satisfactory, and it now depends upon the second cuttings as to whether any increase on last year's yield will be shown by the final figures. Kurpah, of excellent quality, continues in good supply, but as shipments from Madras are now practically at an end for the season, consumers should make their choice while the good lots are still available. Guatemala and Java continue in small supply, and still realise relatively high prices.

Deliveries from London to August 8 were 1,953 chests and 470 serons, against 22,034 chests and 506 serons last year. Stocks in London on August 9 were 2,740 chests and 248 serons, against 2,859 chests and 578 serons last year.

WESTERN PIGMENT CO., LTD.—Registration has been made of a first mortgage debenture for £2,500., dated July 12, 1907, charged on the company's property, present and future.

Continental Notes.

In the *Zentral-Blatt für die Kunstdünger-Industrie*, for July 7 and July 21, L. Herrmann writes on the occurrence and metamorphoses of nitrogen in nature. Although there is nothing original in the paper, it gives an interesting and clear account of the manner in which nitrogen compounds are provided for plant life, and the gains and losses of nitrogen in the soil. The new processes for utilising the nitrogen of the air are also briefly referred to.

The issue of July 7 also contains an account by M. Glassenapp on the working up of Central Russian phosphorites. He states that the increased demand for superphosphates, in the face of diminished outputs of raw phosphate in America and Algiers, has caused the price to rise, and that of the jute sacks used for packing is also 40% higher. Under these circumstances he suggests that the low-grade phosphorites of Central Russia might be utilised. In order to make them soluble and consequently available as plant food, they could be heated to a high temperature with lime in the blast furnaces which have proved unremunerative for the production of iron. Alternatively, the iron works might work their Bessemer furnaces by the basic instead of the acid process, and add phosphatic material so as to produce a basic slag rich in phosphorus.

The same issue contains an article on the position of the calcium cyanamide industry, giving a list and brief particulars of the companies that have been formed in the principal countries of Europe to exploit Frank's patents for the combination of atmospheric nitrogen in this form. In Germany, Italy, Austria-Hungary, France, and Switzerland such companies have been formed, and there is also an English firm, the North-Western Cyanide Co., which is erecting a factory at Odde, in Norway.

The composition and behaviour of a number of different samples of commercial factis in admixture with genuine india-rubber are given in the *Chemiker-Zeitung* for July 24. Altogether ten samples of these vulcanised oils were examined, and experimental vulcanisations were made with them, ten parts of each being added to 100 parts of rubber and five parts of sulphur; after vulcanisation they were tested as to tensile strength and oxidation, both with dry and moist air. In most cases the rubbers containing factis were found to be stronger than the pure rubber, and they were not more liable to undergo oxidation. In all cases the oxidation was much more rapid in dry than in moist air, which points to the advisability of keeping rubber articles in a place that is not too dry.

The detection of blood by means of benzidine forms the subject of a contribution by Utz to the same issue, and he recommends the method as being very delicate and sure. By means of it blood can be detected even when diluted with several hundred thousand times its volume of water. The reagent is made by dissolving the benzidine in glacial acetic acid and adding hydrogen peroxide; it must be prepared the same day as used, else it is not so delicate. When a solution containing blood is added to it, a green or blue coloration is formed. The reaction is not given by solutions of iron, but it is given by pus.

F. W. Himrichsen writes about a method for the volumetric determination of titanium, depending upon the reduction of ferric salts to ferrous by titanium trichloride or sulphate, which is thereby oxidised to the tetravalent state.

The autogenous welding of aluminium is described in the issue of July 27 by M. U. Schoop. As a flux he uses only chloride of lithium, sodium, or potassium, made into a thick paste and spread over the ends that are to be welded. This serves to remove the coat of oxide on the metal and protects it from the air. As no foreign metal is used, electrolysis cannot be set up, and the joint will last under water indefinitely. The joints are almost as strong as the body of the metal. The possibilities of the application of such a process are, of course, almost unlimited, as the use of aluminium for many purposes has only been restricted by the impossibility of joining it except with rivets or screws. For heating the ends up to the melting-point, the oxygen-coal gas or other similar flame is used. For electric conductors there is especially a good opening for the use of aluminium, as it is not only cheaper than copper, but also so much lighter that there is a considerable saving in the cost of the supports.

In the same issue, W. Fahrion has a short controversial note on the chemistry of the formation of leather.

IMPORTS OF CHEMICALS, DRUGS, DYES, AND COLOURS.

THE following returns, which are taken from the foreign and colonial statistics of the United Kingdom, give the amount and value of chemicals, drugs, dyes, colours, etc., imported during July, 1907, as compared with July, 1906:—

ARTICLES.	QUANTITIES. Month of July. 1907.	QUANTITIES. Month of July. 1906.	VALUE. Month of July. 1907.	VALUE. Month of July. 1906.

THE BRITISH ASSOCIATION.

SECTIONAL PROCEEDINGS.

SECTION B.—CHEMISTRY.

THE PRESIDENT'S ADDRESS (*Concluded from page 120*).

HAVING given a short summary of the present state of knowledge on one particular chemical topic, I may perhaps be permitted to conclude my address with a few general observations relating to the science as a whole.

The contemplation of such a life as that of Berthelot makes us realise in a vivid way the progress of chemical science. He was a chemist without limitation, his activity extending over the whole range of the science, physical, inorganic, and organic. Whilst we must not forget his exceptional powers, we cannot help feeling how different in its extent was our science when he entered upon his labours from what it was when they ceased, and we cannot help feeling how vain it now is for anyone to hope for so imperial a sway.

Yet it is difficult to believe that the state of chemistry can ever have been more interesting than it is at the present moment, or that anyone who sighs for the good old times can do so from anything but the love of a quieter life. We need not go back more than twenty years to find a sharp contrast. At that time there was indeed no want of activity, but it was that of a band of travellers who had left their frontier adventures far behind, and were marching steadily over a wide and almost uninterrupted plain. To-day we are among the mountains, with new peaks and prospects appearing on every side. Truly a steady head is required; and well may we ask, Whither are we going, and where is the path of progress and of safety? I rejoice to live in such times; but I feel no competence to describe them, still less can I pretend to have vision keen and comprehensive enough to let me figure as a guide.

One of the penalties of devotion to a progressive science is the constant feeling of being left behind, and the knowledge that, while we are attending to our personal task, things are happening, near or far, that may, for all we know, be affecting the simplest facts and the most elementary principles on which we have been accustomed to rely. This is a feeling that may well prevail at the present day. At the same time I do not think there is any occasion for panic, and I cannot help regretting the somewhat sensational language that has been used, even within our own circles, in regard to recent discoveries. The revelations attendant upon the investigation of radio-activity do indeed mark a distinct epoch in the history of chemical discovery, but that they entail anything like an unsettlement of our scientific articles of faith is not to be admitted for a moment. They make us realise in perhaps a not unprofitable way that scientific knowledge and scientific theories are necessarily proximate, never ultimate, and that ideas which may have been entertained for a long time without modification, and so have begun to seem perpetual, are, after all, only provisional.

There is certainly some embarrassment on finding that a substance like radium, which according to the conventions would be called a chemical element, breaks up so as to give substances which, according to the same conventions, are likewise called elements. But the confusion is one of terminology and not of ideas. I think it likely that few chemists of my own generation have been in the habit of regarding the conventional elements as the ultimate compositional units of matter. We know that in our own country distinguished men of science like Sir William Crookes and Sir Norman Lockyer have always insisted on the complex nature of the elements, and I suspect there are many among us who might own to having made sober, if unsuccessful, attempts at the resolution of elements before the days of radium.

The perplexities of chemists at the present day do not come, I think, from the novelty of the ideas that are being presented to them, but from the great rapidity with which the whole science is growing, from the invasion of chemistry by mathematics, and, in particular, from the sudden appearance of the subject of radio-activity with its new methods, new instruments, and especially with its accompaniment of speculative philosophy. There is an uneasy feeling that developments of great importance to the chemist are being made by experiments on quantities of matter of almost inconceivable minuteness. Spectrum analysis of course took chemistry beyond the limits of the balance, but the new materials which it disclosed could at least be accumulated in palpable quantity. With radio-activity we seem, in relation to the ponderable, almost to be creating a chemistry of phantoms, and this reduction in the amount of experimental materials, associated as it is with an exuberance of mathematical speculation of the most bewildering kind concerning the nature, or perhaps I should say the want of nature, of matter, is calculated to perturb a stolid and earthy philosopher whose business has been hitherto confined to comparatively gross quantities of materials and to a restricted number of crude mechanical ideas. He is tempted to think of Falstaff's reckoning and to exclaim with Prince Henry, "Oh, monstrous! but one halfpennyworth of bread to this intolerable deal of sack!" Experimental science has latterly been spun to greater and greater fineness, until in the region of the X-rays the objective element seems to have disappeared altogether.

I should, however, gravely abuse the position in which I am allowed to speak for the moment as a representative of chemists if I failed to express profound admiration for the masterly work which has been accomplished by the pioneers of the science of radio-activity. All that I wish to say beyond that, is in explanation of a certain awe or trepidation which chemists of the older school may feel in the presence of such bold explorers; and I am the more tempted to say something on the subject, because in recent times, before the advent of radium, a good deal has happened which has given chemists occasion to ask themselves whether chemistry was not beginning, as it were, to drift away from them.

The most conspicuous development of the science during the past twenty years has been, of course, on the physical side, and abundant have been its fruits; but it has seemed to demand from chemists habits and endowments which they did not normally possess, and which they could not easily acquire. I was much struck by a remark made to me a few years ago by a distinguished chemist, who is, I think, the most perfect manipulator I have ever seen at work, to the effect that he felt himself submerged and perishing in the great tide of physical chemistry which was rolling up into our laboratories. Now, it is precisely such men that must be preserved to chemistry. Though chemistry and physics meet and blend, there is, I believe, an essential difference between the genius of the chemist and the genius of the physicist, and I venture to think that some insistence on the primary functions of a chemist is not untimely. The chemist's first qualification is that he shall be master of a peculiar craft; his greatest merit that he is a consummate workman; his distinctive power a nicety of discrimination in questions affecting the composition and quantity of materials. He is not given to elaborate theories and is usually averse to speculation; nor has he usually an aptitude for mathematics. Such the normal chemist is, or was, and such I hope he always may be—naked perhaps in some respects, but unashamed.

There seems to be a solicitude in some quarters to make a chemist something more than a chemist, a solicitude which, if gratified, will, I believe, make him something less than one. We are told, for example, that a chemist should be a mathematician. I do not admit it for a moment. Some mathematics he must of necessity have—that has always been admitted—but in proportion as chemistry develops on the mathematical side does it become important, not that our chemists should be trained in mathematics, but that they should be more than ever carefully trained in the art of exact experiment; that their methods of work, their powers of observation, and, if possible, their experimental conscience, if I may use the expression, should acquire a finer edge. There is never more cause for anxiety than when we see a mathematical theory awaiting the delivery of the confirmatory facts, and there is nothing more important for chemistry than the continual recruiting of that old guard which will be ever ready to stand to arms on the appearance of an eager theorist.

I do not for a moment wish to disparage the adventurous spirits within or outside our science, still less do I wish to range myself with those who meet new ideas with mere objurgation or raillery. We must be content to see new alliances and new activities on the frontiers that separate us from other sciences; content to see many new kinds of chemistry arise in which we cannot all effectually participate. Chemistry is becoming bewildering in its extent, and it would be a great misfortune if this led to the notion that every chemist must try to enlarge his ambit to its confines and fit himself for every variety of work. Those of us who have responsibilities as teachers cannot, I think, be too careful, lest in the attempt to secure breadth we may encourage shallowness and fail to give our students that peculiar and time-honoured discipline in exactitude of work in chemistry proper, which has characterised the chemists of the past, and which is infinitely more important than superficial dealings with a great

Digitized by Google

variety of processes and appliances. I confess that I have frequent misgivings as to whether our modern courses of instruction may not tend to turn our chemists more learned in the science and less perfect in the art than was the case under the ancient *regime*. There was, after all, great virtue in the system which often detained a student day after day, or perhaps week after week, on a single problem of chemical composition such as is involved in the exact analysis of fahl-ore. It is not easy to meet all requirements, but I think we shall all agree that, whatever is left undone, we must make a chemist a good craftsman. It is of the utmost importance that those whom we send out to work in the newer fields shall take with them the resources that have proved most serviceable in the old, and I think it is by supplying such men for special service, rather than by attempting to shift the centre of gravity of the whole system of chemical education, that we can best serve the newer interests.

Another perturbation within the chemical camp in recent times has come from the region of philosophy. Even before the days of radium we have been accused of clinging too fondly to our atomic theory and of stating our knowledge too exclusively in terms of that theory. We are said to have drifted into a dogmatism as real as any we ourselves have had to attack, and to shut our eyes to the light which will enable us to orient ourselves truly in the wide realm of thought. The answer that most of us would give would be, that we value our hypotheses according to their productiveness in new knowledge, and that it is, on the whole, perhaps better to over-exalt an hypothesis that is fertile than from high considerations of philosophy to allow our ideas to become so fluid that they can afford no rigid framework for thought. I think that the attempts to view chemical phenomena apart from the atomic hypothesis, interesting as they undoubtedly are, have not made us feel that this hypothesis has either misled us in any matter of fact or obscured any pathway that we might have followed with greater profit. The value of the thermodynamical treatment of chemical problems is attested by its fruitfulness in promoting fresh discoveries; and here we may welcome a valuable adjunct to the atomic hypothesis. But I do not think we are called upon to acclaim a new method of treating old questions unless it promises some more tangible result than an alleged improvement of our intellectual morals.

If, as I have ventured to hint, mathematics brings with it an element of danger into chemistry, I think that the intrusion of metaphysics would give far greater cause for apprehension. Philosophy always stands with open arms desiring a closer embrace of all the sciences, of which she declares herself to be the fond mother, whilst Science, as we understand the term, has stood reluctant, suggesting, as someone has wittily remarked, that she regards philosophy rather as a mother-in-law. It may perhaps be desirable, especially in the present state of things, that scientific men should allow themselves to become a little more interested in deep questions affecting all knowledge, and should at least examine with some care the gifts that Philosophy is so anxious to bestow upon us. I have a fear that otherwise in the elaboration of scientific theory we may find ourselves embroiled in an unequal contest with what I cannot but regard as the traditional enemy—I mean the unmitigated metaphysician—and the suggestion that I make is, to tell the truth, not so much for the hope of gain as from the desire of self-defence and the safe preservation of the methods that have served us so well in the past.

I think the accusation that we delude ourselves into the belief that our hypotheses are final truth is not true of any thoughtful chemist; the great men of science have surely possessed that quality of mind which philosophy would most approve. If, as has often been remarked, Faraday was mathematically-minded though untrained in mathematics, it seems not less true that he stood in the same relation to philosophy. When, for example, he was asked to express his opinions on the atomic theory, he wrote as follows:—

"I do not know that I am unorthodox as respects the atomic hypothesis. I believe in matter and its atoms as freely as most people—at least I think so. As to the little solid particles, which are by some supposed to exist independent of the forces of matter, and which in different substances are imagined to have different amounts of these forces associated with, or conferred upon, them (and which even in the same substance, when in the solid, liquid, and gaseous state, are supposed to have like different proportions of these powers), as I cannot form any idea of them apart from the forces, so I neither admit nor deny them. They do not afford me the least help in my endeavour to form an idea of a particle of matter. On the contrary, they greatly embarrass me; for after taking account of all the properties of matter, and allowing in my consideration for them, then these nuclei remain on the mind, and I cannot tell what to do with them. The notion of a solid nucleus without properties is a natural figure or stepping stone to the mind at its first entrance on the consideration of natural phenomena; but when it has become instructed, the like notion of a solid nucleus, apart from the repulsion, which gives our only notion of solidity, or the gravity, which gives our notion of weight, is to me too difficult for comprehension; and so the notion becomes to me hypothetical, and, what is more, a very clumsy hypothesis. At that point, then, I reserve my mind, as I feel bound to do in hundreds of other cases in natural knowledge."

This is the attitude of mind, I think, of all thoughtful chemists; if they do not exhibit it ostentatiously it is only because it is as disturbing to the proper work of a chemist for him to be constantly dwelling on the inward nature of his hypotheses as it is distracting in ordinary life to have men always talking about their emotions.

Few, I think, will deny that the atomic theory stands to-day as an indispensable instrument for productive chemical work; it has neither had its day nor ceased to be. Physicists have never been quite satisfied with the hard, indivisible ball of specific substance and definite mass which has served chemistry so well. They have given it bells, have made a vortex ring of it, and have indeed done much that few chemists can understand to make it meet the exacting requirements of their science. But to us it has always been the same, what we have done to it has been external; we have given it, vaguely perhaps, a charge of electricity, a store of energy; we have attached the hooks or rods of valency, but we have not meddled with its interior. We are now called upon by chemical considerations of change of composition, as well as by other considerations more recondite, to subdivide our atom, to credit it with an unsuspected store of energy, to consider it a congeries of unsubstantial electrons. We should wish, of course, to know that the evidence is good enough, but otherwise there can be no possible objection from our side; it will undo nothing that has been done, and we may have good hopes it will lead to the doing of many new things in chemistry. The newer theories are in consonance with the old in one most vital point: they afford those mental pictures of phenomena which most of us find indispensable for fruitful work. They do not belong to what Professor Schuster has characterised as "the evasive school of philosophy." "Those," he says, "who believe in the possibility of a mechanical conception of the universe, and are not willing to abandon the methods which from the time of Galileo and Newton have uniformly and exclusively led to success, must look with the gravest concern on a growing school of scientific thought which rests content with equations correctly representing numerical relationships between different phenomena, even though no precise meaning can be attached to the symbols used." Most of us, I think, will take comfort in this pronouncement and rejoice that if our conception of the atom is to be transformed, it may still be represented as having some kinship with what Sir Henry Roscoe's famous examinee described as the "square blocks of wood invented by Dr. Dalton."

Analytical Notes.

THE CONSTITUTION OF AMMONIACAL LIQUORS.*

The features that have claimed attention this year in the laboratory investigations carried on concern the amount and distribution of cyanogen compounds and their estimation, both in the liquors and in their distillation products, especially in coke-oven liquors, which, as shown in last year's report (42nd Annual Report, Table E, pp. 40 and 41; and Table I, p. 46), differ materially from those produced and worked up in gas works residuals plant.

To rehearse briefly, in normal conditions, cyanogen, combined as ammonium thiocyanate, is the product of *secondary* reactions proceeding in the liquors themselves—with access of air oxidation of ammonium sulphide results in the formation of some ammonium polysulphide, which immediately parts with its sulphur to the ammonium cyanide, which latter, as shown by the examination of virgin liquors, is one of the simple products of condensation. The greater the amount of storage for the liquor the longer are the opportunities for operation of the secondary oxidation reactions. In coke-oven works, the storage room being usually restricted, the operations of secondary reactions in the liquors are restricted in like manner, so that; though in such liquors the proportion of total cyanogen to ammonia may be less than in liquors from gas works sources,

the mode of its combination is markedly different, cyanogen volatile as hydrocyanic acid far exceeding, as a rule, that fixed as thiocyanate or ferrocyanide, while the reverse obtained in samples of liquors examined from gas works sources.

Some examination, moreover, has been made of the cyanogen contents of the liquors proceeding from condensation of the steam and fuel gases from the sulphate of ammonia saturators after extraction of the ammonia ; owing to the high proportionate solubility of hydrocyanic acid, these liquors (described in the trade very appropriately as "devil liquors") were found when drawn from the *cold* end of the condensing apparatus to contain this substance in very marked amount, so that the precautions needed in handling such liquors or transferring them from one receptacle to another should be clearly set before the workmen employed by those responsible for the manufacture. I have come across one instance where such cold liquor contained regularly from 0.7 to 1% of this poisonous compound.

In addition to the work carried out by Mr. Linder in perfection of analytical methods and their application to the often difficult conditions found existing in the works, the inspectors themselves have been engaged in applying these methods to the various liquors derived from coke-oven works in their respective districts. Conditions of working vary, and properties of coal vary from work to work, and district to district. Of the bulk of the work, only a summary of average results is presented here in tobular form.

In the first of these tables the analytical results obtained, and the calculations deduced therefrom of the composition of saturator gases, are presented arranged according to the type of oven employed. This appeared, on the whole, to offer the least disadvantages. To have presented results in geographical distribution would have, perhaps, led to misleading conclusions.

In South Wales, for instance, the number of coke-oven works is as yet small. The table, therefore, follows the alphabetical order of arrangement of tables B, E, G, in last year's report.

As regards the second table, averaging results in 24 works situated in widely different parts of the country in various coalfields, comparison may be made with Table E (42nd Report,

Digitized by Google

pp. 40 and 41) compiled from analytical results of samples of liquors in 1905. The proportion of non-volatile cyanogen has increased this year on the average: so, too, has the strength of the liquors produced; this latter feature is usually an indication of effective washing and scrubbing of the gases by a smaller volume of liquor with greater opportunities for recirculation of the latter.

Occasionally liquors are met with where the oven flues are defective, allowing access of fuel gases heating the oven wall into the interior of the ovens themselves. The existence of these defects is usually recognisable during analysis of the resultant liquors. Should the defects be serious, loss of ammonia results, and there is an undue proportion of oxidised secondary products. Phenoloid bodies then also become prominent; the liquors are low in cyanogen content, and sulphur as thiosulphate increases. Periodical analysis of the liquors for characteristic compounds is therefore an extremely valuable aid in the conduct of the process.

In the third table the samples of "devil liquor" have been grouped according to temperature at point of sampling. The results indicate the need of precaution in making provision for handling, transferring, or for disposal of this very noxious and offensive liquid. Where such liquids mix with the effluent from the ammoniacal liquor stills leaving the works, stress has always been laid on the importance of so designing plant that these should be taken off from the plant at the *hottest possible* point in the condensing system. The figures in the table show the progressively decreasing contents of sulphuretted hydrogen and hydrocyanic acid in the liquors as temperature rises. The figures in the last two columns show the superior solubility of hydrocyanic acid at all temperatures over that of the other permanent gases, carbonic acid and sulphuretted hydrogen, and so in what respect the devil liquors are more noxious than the original liquors from which they are derived. The absolute amounts in grammes per 100 c.c. may be compared with those set out in the table of the contents of the ammoniacal liquors themselves.

In the accompanying table are set out results of analyses of samples of liquors at different times and under varying conditions in two individual works where the volatile cyanogen contents of the gases were found to be high.

Mr. Linder's work has continued to be of very responsible character, the problems presenting themselves for solution in the works tests requiring no small ability and ingenuity in adapting analytical methods to the exigencies of works conditions. I have asked him to present his work in a special memorandum.

(*To be continued.*)

Selected Correspondence.

THE NEXT MOST PRESSING EDUCATIONAL REFORM.

(*To the Editor of The Times.*)

Sir,—It may be well, before the long vacation is upon us to state a point of educational reform which ought to receive attention as soon as possible. In the organisation of secondary education—by far the most pressing of real educational questions—there is nothing more sorely needed than a unification, upon a broad, national plan of the various matriculations and school-leaving examinations now conducted in the most illogical way by the various Universities and by various professional bodies. Every headmaster of the secondary schools, both public and private will acknowledge that the muddle grows yearly greater. What with the examinations of Oxford and Cambridge Boards, matriculations, old and new, little-goes, previous examinations, entrance examinations for Civil Service and for the Law bodies and the technical colleges, many of which now hold their own special entrance examinations, the schoolmaster finds every year an increasing incubus in the conflicting claims of this disorganised chaos. It is true that some of the Universities have been forced by the pressure of events into partial recognition of one another's examinations. But it is nothing less than a scandal that the University of London and the University of Manchester, which hold very similar examinations, and which both accept certain other examinations as their equivalent, refuse to recognise one another's matriculations as being mutually equivalent. The thing is more ridiculous when once one perceives that the work of examining the boys of secondary schools to test the quality of their secondary education is not really University work at all. What is wanted is a sensible, universal, elastic system of school-leaving examinations, conducted by Government in conjunction with the masters of the schools, akin to, but certainly not slavishly copied from, the system of Abiturienten examinations of the secondary schools of Germany and Austria. The Universities would thus be relieved, as the Continental Universities are, from this burdensome task. The colleges for higher education, by excluding all who were unable to produce such a maturity certificate from a secondary school, would be relieved of those ill-trained students who at present embarrass and lower their teaching. The professional bodies would have a simple standard of preliminary education, instead of a perplexing and uncertain multiplicity of standards. The public would have a far better test of the relative efficiency and general standing of the secondary schools than it at present possesses. Certainly the University colleges and the technical day schools and colleges would benefit enormously. The London training colleges and London polytechnics (day departments) would be able at once to start from a surer educational basis by refusing admission to all who have not come up to the matriculation standard. At present, this cannot be done because, amid the conflicting and multitudinous examinations, the secondary schools have not before them a clear and definite goal.

May I be permitted to emphasize the pressing nature of this reform by reference to the action of the Institution of Civil Engineers? It is well known that this, the leading professional body amongst engineers in this country, many years ago organised an entrance examination, for students of engineering wishing to join its ranks; and in many other ways it has manifested its interest in the right training of the youth of this country as engineers. Three years ago it appointed a most influential committee to report on the education and training of engineers. This committee, presided over by Sir William H. White, K.C.B., F.R.S., presented in April, 1906, their report, which was unanimously adopted by the council of the Institution. In the forefront of their suggestions the committee placed the following recommendations:—

A leaving examination for secondary schools, similar in character to those already existing in Scotland and Wales, is desirable throughout the United Kingdom. It is desirable to have a standard such that it could be accepted by the Institution [of Civil Engineers] as equivalent to the studentship examination, and by the Universities and colleges as equivalent to a matriculation examination.

Though thus formulated by a most responsible body, representing not only the Civil Engineers, but also the Institutions of Mechanical and of Electrical Engineers, of Naval Architects, of Gas Engineers, of Mining Engineers, and the Iron and Steel Institute, this recommendation has apparently fallen on deaf ears. The Board of Education has utterly ignored it. In this matter we are behind Scotland, Wales, and Ireland. We are, in fact, no further forward than 40 years ago, when Matthew Arnold, one who assuredly looked at the matter from no narrow professional standpoint, uttered the warning: "Organise your secondary education." Secondary education has, indeed, been partially organised; but it lacks definite focus. Meantime the Universities are, in their muddled way, trying to make good the defect; and in so far as they are succeeding, it is by going out of their legitimate sphere and doing that which ought to be done once for all, nationally, as the inherent corollary of secondary education.

I am, Sir, your obedient servant.

SILVANUS P. THOMPSON.

A New Russian Electrolytic Concern.—The Joint-Stock Electrolytic Factories Association is being formed in St. Petersburg to operate in the sense indicated by its title. Capital, £30,000. The organiser is State Councillor A. N. Ratkoff-Roshnoff.

Calico Printers' Association.—The directors announce, subject to audit, that after charging £224,711. for depreciation, repairs, renewals, and upkeep, and £128,000. for debenture interest, the accounts for the year ended June 30, 1907, show a net profit of £424,040., which, with £134,403. brought forward from last year, leaves a balance of £558,444. Out of this sum an interim dividend for the half year ended December 31, 1906, amounting to £75,402., has already been paid on the preference shares leaving £483,041. available to be dealt with for dividends, capital reserve, and such other purposes as may be thought desirable.

THE RUSSIAN CHEMICAL MARKETS.

THE St. Petersburg chemical market report, dated August 2, represents the tendency for the preceding fortnight as featureless. Sulphate of copper is noted at 6 roubles 60-65 copecks per pood; Chili saltpetre, 1 r. 90 c. to 2 r.; superphosphate, 16-17%, at 65-70 copecks; red lead, 4 r 80 c. to 5 r.; bichromate of potash, 8 r. 40-50c.; white lead, 5 r. 5-15 c.

The Riga market for the same period was also without noteworthy feature, and quotations were:—Borax crystals, 4 r. 45-70 c.; white lead, 4 r. 80 c. to 5 r.; sulphate of copper, 6 r. 75 c. to 7 r.; French verdigris, 19 r. to 19 r. 50 c.; Chili saltpetre, 2 r to 2 r 10 c.; Russian turpentine, 3 r. 10-30 c.; superphosphate, 13%-14%, 52-56 c.; bichromate of potash, 8 r. 50-75 c.

Prices on the Warsaw market were:—Borax crystals, 4 r. 90 c.; white lead, 5 r. 80 c.; sulphate of copper, 7 r. 35 c.; Chili saltpetre, 2 r. 18 c.; Russian turpentine, 4 r. 25 c. Superphosphate, 12%-13%, 52 c.; red lead, 5 r. 90 c. Bichromate of potash, 9 r. 60 c.

The chemical market at Odessa is firm, and some items have risen in value, though the demand is reserved. Borax crystals are quoted 4 r. 80 c.; English white lead, 6 r. 5-15 c.; wood spirit, 95%-96%, 7 r. 40-70 c.; sulphate of copper, 6 r. 85 c. to 7 r. 5 c.; Chili saltpetre (unrefined), 2 r. 15-25 c.; bicarbonate of soda, 2 r. 30-40 c.; red lead, 5 r. 35 50 c.; sulphuric acid, 66° B., 1 r. 25 c.; bichromate of potash, 9 r. to 9 r. 20 c., all per pood.

Rosario Nitrate Co., Ltd.—The directors have declared an interim dividend on the share capital of 3%, free of income tax, on account of the financial year to September 30.

Reported Swedish Sugar Combination.—It is reported from Stockholm that the Swedish sugar manufacturers have decided to form a combination with a capital of 135 million kroner.

Will.—The will of Alderman Christopher Kay, of Ravenscroft Hall, Middlewich, for many years connected with the Cheshire salt industry, formerly a partner in the firm of Messrs. Kay and Blackwell, and subsequently managing director of the Cheshire Amalgamated Salt Company (now merged into the Salt Union), has been proved at £136,368.

Copper Mirrors.—In a paper read before the Chemical Section of the British Association, Mr. F. D. Chattaway observed that the importance from the point of view of the health of the workpeople of obtaining a substitute for the tin amalgam used in the manufacture of mirrors has led many chemists to study the conditions under which metals are deposited from aqueous solution. These investigations have, however, usually had for their object the preparation of a liquid which would deposit a uniform and coherent layer of silver over a large glass surface at the ordinary temperature. Liebig was the first to solve this problem satisfactorily, and his method in which milk sugar is the reducing agent was formerly extensively used. Other metals are not so easily deposited, and copper, which from its close relationship to silver one would expect to behave similarly, has never been observed to be so laid upon glass. Although copper mirrors have never been obtained by deposition of the metal from an aqueous solution, Faraday, about the time when silver mirrors were attracting much attention, made the interesting observation that a mirror-like deposit could be obtained by dissolving a little oxide of copper in olive oil and heating plates of glass in a bath of this liquid up to the temperature at which the oil decomposes. The mirrors, however, obtained by Faraday's method, if of any size, are liable to be stained or discoloured in patches by decomposition products of the oil, and they are, moreover, generally lacking in brilliancy. Further, as the deposition of the metal only takes place when the oil decomposes, the process is excessively disagreeable to carry out; and since the oil is spoiled it is also somewhat costly. In the course of an investigation on the oxidation of aromatic hydrazines, the author made the observation that when solutions of cupric oxide are reduced by these compounds the metal is deposited upon the glass in the form of a brilliant coherent film if clear vessels are used. The mirrors obtained by this method are very beautiful, as they show the lustrous red colour of burnished copper, and are as perfect in reflecting surface and as uniform as the similar mirrors obtained by the deposition of silver. It seems probable that this method of depositing copper upon glass could receive important application in the production of objects of art.

IMPORTS OF CHEMICALS, DRUGS, DYES, AND COLOURS IN JUNE.

THE following returns, which are taken from the foreign and colonial statistics of the United Kingdom, give the amount and value of chemicals, drugs, dyes, colours, etc., imported during June, 1907, as compared with June, 1906:—

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in Explosives. Dr C. Claessen, 45, Dorotheenstrasse, Berlin. British Patent, 24,240. April 30, 1906

This invention has reference to low explosives, for use in mines, of the kind which contain alum compounds, and has for its object to obtain explosives of this character by adding to the known constituents of nitrate of ammonia explosives chrome-alum or chrome-ammonia-alum.

The explosives in accordance with the invention, therefore, consist of ammonium nitrate, with or without the addition of other kinds of nitre (potassium nitrate, sodium nitrate, baryta nitrate), one or more carbon media (vegetable oil, animal or mineral fats or oils and resins), cellulose (flour sawdust, tan and the like), nitrocellulose or nitro compounds of the aromatic hydrocarbon series, and one of the double salts containing a high proportion of water of crystallisation, referred to above. Explosives in accordance with the invention may be manufactured within the limits of:—60–70 parts ammonium nitrate; 20–10 parts potassium nitrate; 10–5 parts gun cotton, tri nitro toluol, nitro benzol, nitro naphthalin and so on; 2–5 parts vaseline, oils or resins; 10–5 parts chrome-ammonia alum, or chrome alum.

Improvements in and Relating to the Preparation of Ammoniacal Copper Solutions. A. Lecoeur, 98, Avenue du Montriboudet, Rouen, France. British Patent, 16 442. July 20, 1906.

The inventor claims:—(1.) In and for the preparation of concentrated solutions of hydrated cuprammonium oxide, by oxidation of metallic copper in the presence of ammonia and water, adding to the liquid in the cold a quantity of caustic soda or potash approximately equivalent to the amount of nitrous acid formed during the reaction and dialysing the resulting solution of hydrated cuprammonium to remove impurities. (2.) A form of the process specified in Claim (1), wherein the dialysis of the solution of hydrated cuprammonium oxide is effected contemporaneously with its production, by circulating the liquid under treatment through the oxidation vessel and dialysing apparatus. (3.) A form of the process specified in Claim (1) or (2) wherein ammonia is added to the dialysed solution to compensate for the loss which may be sustained in the dialysis.

Improvements in the Manufacture of Acetone. L. A. A. Pagès, E. C. A. Camus, and R. P. T. Duchemin, trading as Pagès, Camus et Cie, 8, Rue Barbette, France. British Patent, 13,508, 1907. (Date claimed under International Convention, July 27, 1906).

This invention relates to improvements in the process described in the Specification No. 8,757 of 1906, and has for its object the employment of a vacuum in the process of manufacturing acetone described in that specification.

It has been found that if, in place of carrying out the different phases of the manufacture at atmospheric pressure, a reduced pressure is employed, a considerable decrease in the temperature necessary for the reaction is effected. It is thus possible to greatly reduce the expense of fuel, and, moreover, as the temperature of reaction may be thus kept sufficiently low to avoid partial decomposition, either of the acetic vapours traversing the apparatus, or of the acetone produced, a larger yield is obtained and the acetone is purer. The necessary reduction of pressure, the extent of which may vary with the base or acetate employed, may be produced by any suitable means—for example, by a suitable regulation of the condenser or by the arrangement of an aspirator at the outlet end of the apparatus.

The Bank Rate.—On Wednesday last, the Bank Rate was increased to 4½%

Fletcher, Russell and Co.—The directors announce an interim dividend at the rate of 10% per annum on the ordinary shares for the half-year to August 31st.

Manchester Importers and Exporters' Association.—At a recent meeting held at Manchester, and largely attended by merchants and shippers, it was resolved to form, for their benefit, a Manchester Importers and Exporters' Association. A General Committee was afterwards appointed, which held a meeting, on Wednesday last, under the presidency of the Lord Mayor. It was proposed that an Executive Committee of thirty-five be appointed, and that the Committee be instructed to prepare a scheme defining the constitution and general scope of the functions of the Association, and to submit the scheme when prepared to a meeting of the General Committee.

Miners and the Eight Hours Day.—At the Westminster Palace Hotel, on Thursday last, a meeting was held of the Mining Association of Great Britain, and another of the Executive Committee of the Miners' Federation, which were preliminary to a Conference to consider the Government Eight Hours Bill for miners. This conference will take place between the coal-owners and the miners. The Bill has never before been discussed by the two parties, having only been printed about a fortnight ago. If the intentions of both parties are carried out it is expected they will be able to come to an agreement which will enable such amendments to be made in the bill that the measure when it comes up for discussion in the next session of Parliament will be practically an agreed Bill.

BRADFORD DYERS' ASSOCIATION.—The Board has decided to declare a dividend on the ordinary shares for the half-year to June 30 at the rate of 7% per annum.

BROKEN HILL SOUTH SILVER MINING CO.—During the half-year ended June 30, 101,380 tons of crude ore were treated by this company, producing 15,769 tons of concentrates. The ore reserves are estimated at 3,000,000 tons. The total working costs per ton of crude ore were £1. 0s. 5d. £10,637. has been written off for depreciation, and the net profits for the half-year were £93,899. The surplus carried forward is £95,906. and the net liquid assets on June 30 were £102,060. The capital expenditure was £43,102.

THE LABOUR MARKET.—The memorandum prepared by the Labour Department of the Board of Trade for the *Board of Trade Labour Gazette*, states that there was but little difference in the state of employment in July compared with June. As compared with a year ago, most of the principal industries showed some improvement. There was, however, some decline in the engineering and shipbuilding trades. There was a net weekly rise in wages during July of £12,500 per week. In the 273 trade unions, with an aggregate membership of 631,158, making returns, 23,291 (or 3.7%) were reported as unemployed at the end of July, 1907, compared with 3.6% at the end of June, 1907, and 3.6% at the end of July, 1906.

The Companies Bill.—In moving the second reading of this Bill, in the House of Commons, Mr. Lloyd-George stated that it embodied the recommendations of the Select Committee appointed by Mr. Gerald Balfour. The principles underlying the Bill being fully explained in the memorandum, he thought it unnecessary at that time to go through the clauses. The Bill had been thoroughly handled and discussed in financial circles. There were, however, some clauses which had excited controversy, and these the Government did not propose to proceed with in the hope that the Bill might pass as an agreed measure. One of the clauses which would thus be dropped was in regard to the filing of accounts of private companies, and another was a provision which seemed to make it impossible for gentlemen who now audited the accounts of some concerns, and who were not accountants at all, but were appointed as experts, to continue to do so.—Mr. Fell, whilst admitting that the Act of 1900 required considerable amendment, called attention to some points of which careful consideration would be necessary in Committee.—Mr. Beale said a body of lawyers of considerable eminence in this country had serious points to submit for consideration; and this could not be an unopposed Bill in the sense that it could be disposed of in a short time.—Lord R. Cecil said it was unfortunate that such an important measure should have to be considered at that hour. The danger of certain restrictions was that they hit the honest fool and missed the clever rogue. The foolish investor, in whose interests the provisions were made, imagined that the Legislature had fully protected him, while some ingenious swindler found his way round them, and the last state of the investor was worse than the first. He earnestly pressed on the Government to consider whether it was really in the interests of the public to impose restrictions on the formation of companies.—Mr. Hills said the true line of company reform was to increase the responsibility of directors.—The Bill was read a second time.

Brunner, Mond and Co. and their Employés.—It is announced that the directors of Messrs. Brunner, Mond and Co. have decided to add sixpence to each pound earned during the year by those engaged by them for two years, and one shilling per pound to those whose service extends over six years. The sum will be placed to their account annually, and interest at 3% will be added. The scheme comes into operation as from last December.

Wages in the Coal Trade.—The Coal Conciliation Board for the federated mining districts in England and North Wales agreed on a further 5% advance in miners' wages from the first making-up day after September 13. This is the third advance of 5% which has been made during the present year, and brings wages up to 55% above the standard, or only 5% below the maximum fixed when the present agreement was made. When the Board met a month ago to consider the demand for an advance they found that they were unable to agree, and the employers promised that they would have the statistics ready for the meeting on Wednesday. Since the meeting the South Wales miners, who were only 2½% below the rates paid in the federated area, have received an advance of 5%, and the Northumberland miners have also received an advance. The Welsh miners are within 2½% of their maximum, while the federated area was still 10% below.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, July 30, 1907.

(Rate of Exchange, $4.87¼ = £1.)

Nitrate of soda remains firm, at $2.50. per 100 lbs. Sulphate of ammonia is dull at $3.05. per 100 lbs. Grey muriate for galvanising remains unchanged at 6c. to 6¼c. per lb., as to make. White electrical muriate is cheaper, at 5¾c. to 6¼c. per lb. Lump sal ammoniac is steady at 9¼c. per lb. for good white seconds. Lump carbonate of ammonia is 7¾c. to 8c. per lb. Bleaching powders are dull, and in rather plentiful supply. Alkali and caustic soda are both quite without new features, at prices previously quoted. Sulphate of copper, although held by the Syndicate at 7c. per lb., is offered at 6¾c. per lb. by outside makers. White powdered arsenic is quite dull but firm, at 7⅛c. to 7¼c. per lb. Red Saxony arsenic is steady at 7¼c. per lb. Calcined potash, 80-85%, is 3¾c. Hydrated is 4¾c. to 5c. per lb. Caustic potash, 75%, is 4¾c. Chlorate of soda is 8½c., and potash 8¾c., f.o.r. works. Bichromate of soda and potash are 7⅛c. and 8⅜c. per lb., under Syndicate control. Prussiate of soda is 9⅜c. and potash 10c., with business rather slow. Oxalic acid is 8¾c. Needle antimony is 8½c. for spot, and 7c. for shipment, while oxide is quoted at 11½c. for shipment.

TAR AND AMMONIA PRODUCTS.

Friday.

Benzols dull, with values given at 8d. to 8¼d. for 90's, and 8½d. to 9d. for 50-90's. Crude tar, 15s. 6d. to 20s. per ton, Thames, 1¼d. to 1⅜d. per gallon delivered; refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, London, 26s. to 26s. 6d., f.o.b.; Gas Company, 29s.; East Coast, 25s. to 25s. 6d.; West Coast, 24s. to 24s. 6d., forward 2s. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 10½d. to 11d.; pure, 1s. 6d. to 1s. 7d. Carbolic acid, crude 50%, 1s. 5½d. to 1s. 5⅝d.; 60%, 1s. 8d.; 75%, 1s. 11¾d. to 2s.; crystals, 39-40, 5¾d.; 34-35, 5⅝d. Cresylic, 95%, 1s. 1d. to 1s. 1¾d. Anthracene, 40 to 45%A, 1¾d. to 1¼d. Pyridin, 4s. 3d.

Sulphate of ammonia quiet. Nearest values are:—Beckton, £12.; Beckton terms, £11. 12s. 6d. to £11. 13s. 9d.; London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 16s. 3d. to £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d.; Liverpool, ordinary, 11s. 3d. and refined, 11s. 4½d. Official quotations:—Cargoes off coast or due, 11s. 1½d.; ditto for prompt shipmen, 11s. 6½d.

FERTILISER MATERIALS.

THURSDAY.

Quietness still prevails in all markets for manure material.

East Indian bone meal for shipment is easier, £4. 17s. 6d. per ton, nett, c.i.f. terms Liverpool, would probably now be accepted for 4½ and 52%. Bombay quality; on spot, £5. 5s. to £5. 10s. per ton, according to quality, is required, ex store.

Nitrate of soda moves very slowly, but quotations remain steady at 11s. 1½d. per cwt. for 95% and 11s. 4½d. per cwt. for refined quality, ex store.

There is no change to report in mineral phosphates, the position remaining very firm.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: Standard brands, £78. to £78. 5s. cash, and £75. to £75. 5s. three months. Tin: G.M. quality, £164. 5s. to £164. 15s. cash, and £163. 15s. to £164. 5s. three months; English, £168. to £169. Lead: soft foreign, August delivery, £19. 17s. 6d.; August-September, £19. 15s.; October, £19. 12s. 6d.; November, £19. 10s.; English, £20. 10s. Spelter: ordinary brands, September shipment, £22.; August shipment, £22. 5s. ex ship; hard, £18. 10s. to £19. f.o.b. Antimony, £36. to £38.; ore, £9. to £9. 10s. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 16s. Nickel, £175. to £185. Pig-iron closing prices:—Cleveland, 56s. 9d. cash, and 56s. 6d. one month.

MISCELLANEOUS CHEMICAL MARKET.

FRIDAY.

There is a continued fairly active market in most of the heavy chemicals and raw materials, and prices all round, on the whole, are firm. In the alkali trade there are no changes of consequence. Caustic soda, 70%, stands at £9. 15s., f.o.b. Liverpool. Ammonia alkali firm, at £4. 10s., bags, f.o.r.; and soda crystals, at 60s. Bleaching powder, for prompt and early delivery, at £4. 7s. 6d. to £4. 10s., f.o.r. and f.o.b. Chlorates are unchanged at 3½d. Sulphate of copper is again lower at £29. 10s., f.o.b. Sulphur, best thirds, £4. 12s. 6d., c.i.f. Saltcake, in bulk, is 40s. to 42s. 6d., f.o.r. and f.o.b. Potash, caustic and carbonate, are still in good request, and prices are steady at former quotations. Borax is unchanged at £15. per ton. Grey acetate of lime firm, at £12. 10s., c.i.f.; and acetic acids are practically unchanged at former quotations, though rather more freely offered. For sugar of lead there is very quiet demand. Prussiates are more active, and there is better inquiry, both for prompt and forward delivery; soda at 3¾d., and potash at 5¾d. Arsenic still fairly active, at £31. 10s. to £32. per ton. There is continued good demand for ammonia and ammonia salts.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

OILS.—Palm oil steady. Olive oil quiet at £37. 10s. to £38. 10s. for Levant, according to quality. Linseed oil dull, at 31s. 6d. to 32s. for Liverpool refined in export barrels. Cottonseed oil, 31s. 6d. to 32s. per cwt. for Liverpool refined in export barrels. Rosin quiet, with limited business passing at recent quotations. Tallow dull at 34s. per cwt., c.i.f. for South American mutton. Turpentine quiet at 41s. 9d. per cwt. on spot. Petroleum, firm, at 6¼d. for Russian and Roumanian, and 7d. to 8d. for American refined oils. Petroleum spirit steady, at 1s. 0½d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes quiet. Pearl ash nominal. Bark dull. Logwood and fustic also quiet. Cutch inactive, with limited supplies. Gum arabic steady. Castor oil steady at 3 5/16d. for good seconds Calcutta, 3 11/16d. for first pressure French, 3½d. for second pressure French, and Calcutta 3¾d. for August-September shipment. Gambier steadily held at 18s. 3d. for block, and arrival parcels quoted at 18s. for June-July, July-August, and August-September shipment; spot parcels of cubes 28s. 6d., and 27s. 9d. to 28s. for August-September shipment. Shellac dull at 204s. for fair TN orange on spot. American powdered starch 10s. on spot, and 9s. 6d. c.i.f., for shipment; pearl, 9s. 6d. on spot, and 9s. c.i.f., for shipment. Glucose: American liquid, 43%, 10s. 4½d. on spot, and 8s. c.i.f., for shipment. Cream of tartar, 98% foreign powder, 80s. 6d. to 81s.; 95%, 79s. Tartaric acid: English on spot, 11¾d.; foreign, 10⅝d. Citric acid: English 1s. 11½d.; foreign, 1s. 11d.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—Values during the week have continued to fall, both in linseed and cottonseed oils, the former by 15s. and the latter by 10s. per ton on the week. Seeds also are a weak market, with linseed dropping and cottonseed little changed, with a quiet and very small business passing. Amongst the principal imports here to date, as against the same period a year ago, are:—Wheat, 2,446,477 qrs., against 2,449,845 qrs.; flour, 124,042 cwts., against 232,803 cwts.; linseed, 174,893 qrs., against 324,840 qrs.; rapeseed, 60,696 qrs., against 48,898 qrs. Cottonseed, Egyptian, 122,221 tons, against 107,061 tons; other kinds, 110,808 tons, against 91,776 tons. Oilcake, 17,557 tons, against 25,730 tons; hemp, 84,579 cwts., against 109,383 cwts.; olive oil, 3,439 tuns, against 2,872 tuns; tar, 3,599 brls., against 4,725 brls. Refined cotton oil quiet, at 27s. 9d. spot, naked; August, 27s. 6d.; September-October, 27s. 6d.; November-April, 23s. 9d.; casks £1., and barrels 27s. 6d. per ton extra. Exports during the week:—17 tons Belgium, 14 France, 32 Germany, 27 Holland, and 2 Norway; total, 92 tons. Cottonseed remains unchanged, with imports during the week of 5,061 tons. Linseed oil flat at the reduced prices, spot, naked, 21s. 9d.; September-December, 21s. 1½d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports for the week:—115 tons Australia, 2 Belgium, 1 Egypt, 10 Germany, 7 India, 4 Norway, 2 Turkey; total, 141 tons. Linseed, Calcutta, 6d. lower; Plate, 3d. to 6d. lower. Imports during the week have been:—50,375 qrs. Turpentine, American, 42s.; Russian, easier business done at 20s. 6d. Rosin, from 11s., quiet. Castor oil, November-December, 30s. 6d.; January-June, 30s. 9d. for first pressure. Olive oil, £41. to £42. Cod oil, £16. to £19.

CAKES.—A steady market at last week's price.

PAINTS.—Unchanged.

TYNE CHEMICAL REPORT.

THURSDAY.

Chemical market steady, but no change to report in prices. Soda crystals, locally, £3. to £3. 2s. 6d. per ton gross weights. Bleaching powder, £5. to £5. 5s. per ton. Caustic soda, 70%, £9. 15s.; and 76-77%, £10. 10s. per ton. Sulphur, firm, at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2 cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett; do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5/7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (saltcake) in bulk, £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market is still very firm, but actual business inclines to be quiet owing to long loading turn and general scarcity of all classes of coal for early shipment.

To-day's current quotations:—Best Northumbrian steam, 16s. to 16s. 6d. per ton; second qualities, 15s. 6d. to 15s. 9d. per ton; small steam coals, 10s. to 11s. per ton; good Durham bunkers, 14s. 3d. to 14s. 6d. per ton; coking coals, 14s. to 14s. 6d. per ton; household coals, 16s. to 17s. per ton; foundry coke, 25s. per ton; gas coke, 20s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Thursday.

For the new contract and delivery season, from now on to March 31, 1908, the Scottish mineral oil companies have agreed to charge their burning oils at from 6¼d. to 6½d. (see below) per gallon. In the case of No. 2 quality, however, the contract sales are to be under certain restrictions and within certain limits as to quantity. These figures represent a substantial improvement of the contract prices which ruled during the greater part of the foregoing season, 1906-1907. The other Scottish paraffin lines are all quite steady, at values for some time easily maintained. In the general chemicals the same slightly improving tendency as to movement continues, both as regards prompt and forward business, and with values steady. In sulphate of ammonia, Leith f.o.b. deliveries, the comparative steadiness of feeling remains, to-day's figure being £12. for prompt, though, as heretofore, with no great bulk passing.

Chief prices current are :—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow ; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool ; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b. Glasgow) ; bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne ; borax, English refined, £16., and boracic acid, £25., nett, Glasgow ; caustic soda, white, 76°, £10. 10s. ; 70-72°, £9. 15s. ; 60-62°, £8. 15s. ; and cream, 60-62°, £8. 15s., all nett, Liverpool ; chlorate of potash, 3½d., nett, Glasgow ; creosote (ordinary coal-tar and blast-furnace), 2¼d., naked, f.a.s. Glasgow ; nitrate of soda, 11s. 3d. ; paraffin scale, hard, 2d. to 2¼d. ; and soft, 2⅜d. to 2½d. per lb. ; paraffin wax, 120° semi-refined, 3d. to 3½d. ; paraffin spirit (naphtha), 10d. to 11d. per gallon ; paraffin oil (burning), special quality, 6¾d. ; ordinary sorts, 6½d. and 6¼d. (new season's contract prices), at Glasgow and other big centres ; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d. ; 885°, £6. 7s. 6d. to £7. 7s. 6d. ; 890-895°, £7. 2s. 6d. to £8. 2s. 6d. ; prussiate of potash, 6d., nett, f.a.s. Glasgow ; salammoniac, first and second white, £42. and £40., less 2½% any port ; saltcake, 40s. to 42s. 6d. ; soda ash, £5. 10s. to £5. 15s., nett, Tyne ; soda crystals, £3. to £3. 2s. 6d. ; sulphate of ammonia, £12., prompt f.o.b. Leith ; sulphate of copper, £30. 5s., less 5% Liverpool, prompt.

New Companies.

New Oil Refining Process, Ltd.—Capital £50,000., in £1. shares. This company has been formed to adopt an agreement with J. Noad, E. J. Townsend and W. McMullen, to which the Burmah Oil Co., Ltd., is to be a party, for the purchase of certain patents and patent rights, and to carry on the business of producers, refiners, storers and distributors of and dealers in petroleum and its products, etc. No initial public issue. The first directors are J. T. Cargill, J. Hamilton, E. J. Townsend and W. A. McMullen ; remuneration (except managing director) £150. each per annum. Registered office, Dixon House, Lloyd's Avenue, E.C.

United Egyptian Salt, Ltd.—Capital £300,000., in £1. shares. This company has been formed to adopt agreements (1) with the Egyptian Salt and Soda Co., Ltd., and the Port Said Salt Association, and (2) with the Egyptian Markets, Ltd., the Egyptian Salt and Soda Co., Ltd., and the Port Said Salt Association, and to carry on the business of salt and general merchants. No initial public issue. The first directors are to be appointed by the subscribers ; qualification £100. ; remuneration £250. per annum divided. Registered office, 1, Frederick's-place, Old Jewry, E.C.

Sungei Choh Rubber Estate Co., Ltd.—Capital £45,000., in £1. shares. This company has been formed to acquire and develop the Sungei Choh Rubber Estate, containing about 2,069 acres in Selangor, Federated Malay States, to adopt an agreement with Loke Chow Thye, L. R. Yzelman, Loke Chow Kil and N. Dalrymple, and to carry on the business of planters, growers and cultivators of rubber and other produce, etc. Minimum cash subscription 20% of the shares offered to the public. The first directors are A. Thomson, A. R. Venning, N. Dalrymple and R. B. Heinekey ; qualification £250. ; remuneration when dividends do not exceed 6%, £60. each per annum, with an additional £10. each for every additional 1% dividend in excess of 6%.

LATE ADVERTISEMENTS.

TECHNICAL Chemist, at present engaged, but desiring a change, is open to negotiate with firm requiring first-class man as Works Manager. Advertiser, who has filled responsible and important positions, is well up in pure and applied chemistry and in chemical engineering, having had an exceptionally wide and varied manufacturing and commercial experience in connection with chemical trade; would be specially useful to any firm seeking to extend their manufacturing operations. Communications to be strictly confidential.—Reply, Box "1,479," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

GRADUATE of a London Technical College desires Post as Assistant (Laboratory or Works), preferably metallurgical. Experience Works and Laboratory abroad; moderate salary.—"1,478," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed, and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**

Half-Yearly (26 numbers) ..... **6s. 6d.**

Quarterly (13 numbers) ..... **3s. 6d.**

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

CURRENT TOPICS.

THE CANAL PROBLEM.

THE deliberations of the Royal Commission on Canals and Waterways are now sufficiently complete to justify some forecast as to the probable result of the investigations. The conclusions at which the Commission may arrive will indicate the direction which legislation may take, and in an article in the current number of the *Financial Review of Reviews*, Mr. L. F. Vernon-Harcourt, M.A., M.I.C.E.,—a leading authority on inland waterways, shows how far the conclusions of the Royal Commission may affect the future prospects of the canal companies. Mr. Vernon-Harcourt was for many years Professor of Civil Engineering at University College; he has been to India to report on the River Hugli to the Calcutta Port Commissioners; was British member of the International Jury in Vienna on projects for canal lifts; a Government delegate to the Milan Navigation Congress of 1905; and last year was made a British member of the Suez Canal Works Consultative Commission.

After summarising the efforts which had been made in recent years to resuscitate inland navigation in this country, Mr. Vernon-Harcourt observes that an inquiry into the conditions affecting the traffic by water in the countries in Europe possessing the most developed systems of inland navigation, demonstrates that, in view of the unfavourable physical conditions in England for the extension of inland waterways, it would be useless to attempt making improvements, except where large quantities of bulky goods require to be conveyed to large centres of trade, or to ports with access to the sea, or where, like Birmingham, a large inland town, possessing a suitable trade, would be materially benefited by a waterway affording it a convenient and economical mode of transport to a navigable tidal river. Owing to the extensive seacoast of England in proportion to its area, and the large estuaries and tidal rivers with which it has been endowed by nature, improved in some cases by engineering works, most of the large towns, such as London, Liverpool, Hull, Bristol, Newcastle, and Sunderland, and recently Manchester by its canal, have ready access to the sea; whilst the coalfields of South Wales are accommodated by the numerous Bristol Channel ports, and some of the iron industries of the North by the ports of Barrow and Middlesbrough. These circumstances greatly limit the scope for inland navigation; whilst the salt mines of Cheshire have already been fully provided for by the successive improvements in the Weaver Navigation, and some of the collieries of Yorkshire by similar works on the Aire and Calder Navigation.

Any attempts to revive inland navigation throughout England (continues the writer) could only prove abortive; and the only waterways to which attention may be directed

Digitized by Google

with advantage, with the object of improving their capabilities for traffic, are the Grand Junction Canal connecting London by water with the Midlands, the Stafford and Worcester Canal, the Leeds and Liverpool Canal, the waterway from Sheffield to the Humber, the canals clustering round Birmingham, and those passing through the Potteries and accommodating the northern mining and manufacturing districts; whilst provision should be made for putting Birmingham in connection with the sea by a commodious waterway. Nearly all the waterways within the district bounded by the Birmingham and Shropshire Union Canals, the Leeds and Liverpool Canal, the Aire and Calder Navigation, the Don Navigation, a line d awn from Sheffield to Stoke, and the Trent and Mersey Navigation from Stoke to the Birmingham Canals, have a large traffic at the present time, in spite of a great want of uniformity, and inadequate dimensions in many cases, showing that they accommodate a suitable trade for waterways; and if they could be enlarged and given uniform dimensions at a reasonable cost, the trade of the district would be much benefited. The problem of connecting Birmingham by a good waterway to the sea is a difficult one, on account of Birmingham being situated in the centre of England, and about 400 feet above sea level. The easiest and much the shortest route is to the River Severn, following the line of the Birmingham and Worcester Canal, where, after passing through some tunnels in the first thirteen miles of high level from Birmingham, it falls in the next seventeen miles to the Severn. The route to the River Weaver, and thence to the Mersey, would more nearly coincide with the present main course of trade from Birmingham, and would accommodate other places on its route; but it would involve a canal rather over twice the length of a canal to the Severn, and would have to surmount two summit-levels, involving considerable differences in level before beginning to descend about 400 feet to the Weaver. A canal from Birmingham to London along the line of existing canals, besides being twice the length of a canal to the Weaver, would equally necessitate surmounting two summit-levels, with considerably greater variations in level, and therefore need not be considered.

By restricting schemes of improvement to the waterways enumerated above, all would be done for promoting inland navigation in England which could be reasonably expected to be financially practicable; and Birmingham, which has gone to South Wales for its water supply, might advantageously take up the problem of obtaining connection by water with the sea; and if, on careful investigation, it should be found that a canal could be constructed at a cost not exceeding its advantages direct and indirect, the Birmingham Corporation should be able without difficulty to raise the necessary funds. Railway shareholders need have no apprehensions that any revival of inland navigation in England will appreciably injure their interests, for if conducted on a large scale it must inevitably result in failure; whereas if confined to the districts where the traffic is liable to be congested by the carriage of bulky goods, it will tend to relieve the railways of that special district from an excess of its least remunerative traffic, and by extending facilities of transit where most needed, it will be calculated to promote the trade of the country with benefit to all interests concerned. A commodious waterway from Birmingham to the sea might for a time reduce the bulky traffic on the lines now giving it access to seaports; but before long the extension of the trade of Birmingham likely to arise from increased facilities of transport would doubtless restore the balance.

Mr. Vernon-Harcourt concludes:—"The future of English waterways, as indicated in the improvements proposed, based upon the foregoing considerations, derived from a study of the conditions of Continental waterways, is, indeed, not nearly so bright and far-reaching as the most ardent advocates of inland navigation in England picture to themselves; but the works suggested, limited to districts affording good prospects of a large traffic in bulky goods, are the only ones likely to be attended with successful results, and with benefit to the general trade of the country. The Government could advantageously assist in the accomplishment of these objects by facilitating the requisite amalgamations and unification of control of the waterways to be improved, and the obtaining of the necessary powers for carrying out the works; whilst for schemes for affecting these improvements, which after thorough investigation proved perfectly sound, loans on easy terms might be granted for providing for the expenses of the works."

NITRATE OF SODA.

Business is at a complete standstill, with buyers and sellers wide apart as to values. The market is nominally firm at the equivalent of 11s. per cwt. on spot in Hamburg, and producers ask 9s. 2d. per quintal, f.o.b., for autumn shipment from Chili, but the latter figure, with freight at 15s. per ton, is considerably higher than that at which the same nitrate is freely offered for spring delivery in Europe. All ports are heavily stocked, both on the Continent and in the United Kingdom, larger quantities being warehoused in London and Liverpool than for many years past; holders would accordingly make concessions except for the fear of spoiling the market ahead. The dearness of money in Germany, and the consequent difficulty in financing cargoes, have led to the ordering of many ships to Antwerp, Rotterdam, and Dunkirk, instead of to Hamburg, the largest emporium for the Chilian fertiliser. The August shipments from Chili to Europe are estimated at 88,500 tons, or about the same as last year, and the first direct consignment to Egypt (6,400 tons) has just been effected by steamer. The mysterious curtailment of the output of nitrate of soda was repeated last month, when only 154,977 tons are said to have been produced, compared with 155,514 tons in July, 1906, although the number of "oficinas" had increased from 113 to 129; four of these—Candelaria, Carmen Alto, Florencia, and Luisis—commenced operations in June, producing 6,000 tons of nitrate.

GERMAN STRIKES AND LOCKOUTS.

THE statistics of strikes and lock-outs in Germany in the year 1906 which the Imperial Statistical Department has recently published show that the total number of labour disputes which came to an end in the twelve months was 3,626, of which 3,328 were strikes and 298 were lock-outs. This compares with preceding years as follows:—

1899	1,311	1903	1,444
1900	1,468	1904	1,990
1901	1,091	1905	2,687
1902	1,106	1906	3,626

In only one of these years was there a drop, and that year (1901) was a year of commercial and industrial depression in Germany. In 1906, on the other hand, not only did the number of labour disputes reach a maximum, but the difference between that and the preceding year was the greatest on record, viz. 969.

THE GERMAN CHEMICAL TRADE IN 1906.—II.*

By Consul-General Sir William Ward.

THE recovery of trade which set in about three years ago in Germany further maintained itself during the year 1906, and the somewhat pessimistic apprehensions entertained in some quarters concerning the probable effects of the new German customs tariff, as well as of the new commercial treaties concluded recently between Germany and several other States, upon commercial and industrial interests in this country, have, so far at all events, not been realised. Favoured by the peaceful political condition of most parts of the world which prevailed during the past year, all branches of German industry experienced a further considerable development, which was on the one hand the cause and on the other hand the effect of the increased activity in the trade and shipping of this and of the other trading commercial seaports of Germany during the year 1906.

HAMBURG.

Cement.—The present position of the German cement industry is considered to be upon the whole satisfactory. At the end of last year the works existing in this country were employed to the utmost of their capacity, and the firms at Hamburg and elsewhere who were engaged in the cement trade are said to have done a fairly profitable business. Very considerable quantities of German cement were last year again exported from this country for the account of Hamburg firms, though a large portion of the amount shipped from this port is merely transit trade for the account of the German factories situated in the interior.

The total number of larger cement works at present existing in Germany is stated to be about 80, while there are besides these a very large number of works of less importance. Of the various groups of German cement works formed many years ago according to their geographical position some had recently been dissolved, but they have now all become reunited. The conditions under which the works forming these different groups have combined together are not in all cases the same, for whilst several bear the character of a trust and the sale of the products of the works belonging to each group is left to a syndicate, the factories belonging to other groups attend themselves to the sale of their products, and are merely obliged to keep to the sale prices agreed upon between all the various groups of German cement works.

The exact extent of the total German cement production in 1905 is not, at present, ascertainable; it may, however, be roughly estimated at 15,000,000 casks (of 170 kilos. each), and it may be regarded as probable that the production in 1906 has been still greater.

Considering that the number of cement works now existing, not only in Germany, but also in the United Kingdom, France, and Belgium, without mentioning other European countries, is such a large one, and that the total cement production in all parts of Europe has been increasing from year to year, the necessity of finding fresh markets for this constantly expanding output is naturally felt also by the German cement industry to be a question of urgent importance.

The following figures will show the total annual quantity and value of the export of cement from Germany during each of the six years 1900-05, viz.:—

Year.	Quantity. Tons.	Value. £	Year.	Quantity. Tons.	Value. £
1900	600,386	1,271,900	1903	742,381	900,500
1901	560,612	921,700	1904	635,248	836,300
1902	699,378	999,800	1905	675,664	890,500

It will be seen that whilst with certain fluctuations the total volume of the exports of cement from Germany has increased during the six years 1900-05 by about 75,300 tons, the value has decreased by £381,000., thus showing the considerable fall which has taken place in price.

During the same period the total cement exports from the United Kingdom (according to Board of Trade Returns) have been as follows:—

Year.	Quantity. Tons	Value. £	Year.	Quantity. Tons.	Value. £
1900	673,000	—*	1903	399,988	676,752
1901	584,000	—*	1904	384,583	632,356
1902	521,000	—*	1905	456,558	721,786

* Not known.

* Special abstract of the British Consul-General's Annual Report on the Trade and Commerce of the Consular District of Hamburg for the year 1906.

The principal markets for British cement, in order of their importance, are:—British India, South Africa, Canada, New Zealand, the Argentine Republic, Brazil, Australia, and the United States of America, etc., whilst the principal markets for German cement are the Netherlands, the United States of America, Belgium, Brazil, Austria-Hungary, South Africa, Denmark, etc. Until a few years ago the United States of America imported very much larger quantities of cement, both from the United Kingdom and from Germany, than at present; but during recent years, as is well known, the cement industry in that country itself has been rapidly growing in importance, and from being merely a country of import the United States of America have now become one of export, and have even of late begun to enter into competition with other exporting States, for instance to South America, where the consumption of foreign cement is now increasing from year to year

Potato Products.—The total area in Germany under potato cultivation in 1906 was 0.44 per cent. less than in 1905, but the total yield was 42,936,702 tons against 48,323,353 tons in 1905. The exports from Germany of potato starch amounted in 1906 (10 months) to 377,150 cwts. against 130,071 cwts. in 1905, and the exports of dextrine to 154,269 cwts. against 141,314 cwts. in 1905. Business in potato products is, however, considered to have been dull, and the export business is said to have been seriously hampered on account of the increased production in the Netherlands and of the difficulty experienced by German starch factories in obtaining potatoes upon favourable terms. The production of grape sugar (including the liquid variety) largely exceeded that of 1905, but business was dull throughout the year.

Oils.—There was a rise in prices for all classes of oils and fats, with the exception of linseed oil, which was steady and remained the cheapest vegetable oil. The imports of linseed amounted to 1,039,000 tons against 1,059,000 tons in 1905. The imports from India amounted to 217,000 tons.

Germany's demand for olive oil for technical purposes was, in the course of 1906, supplied almost exclusively from Crete, where the output was far greater than in any previous year. The total imports of olive oil to Hamburg in 1906 were considerably less than for several years past, viz., 8,756 barrels, of which 6,619 barrels came from the Levant, including Crete.

The production of steam train oil in 1906 was unusually prolific, and was even somewhat in excess of 1905. There appears to be a large increase in the use of this oil at low prices. Crude medicinal train oil was little manufactured, and appears to be little in demand in consequence of the low prices of steam train oil. There was, for the same reason, a falling-off in the sales of white and brown medicinal oil. The total imports in 1906 of brown train oil were 6,500 barrels (against 8,500 barrels in 1905), of white train oil 156,200 barrels (against 92,800 barrels), of medicinal steam oil 6,400 barrels (against 6,800 barrels), and of crude medicinal oil 900 barrels (against 1,900 barrels in 1905).

Wax.—Business in beeswax is said to have developed during the last few years in an unusually favourable manner, so that Hamburg's leading position in this commodity was still further strengthened. Imports increased some 25%, and business was throughout the year satisfactory. The total imports from foreign countries amounted in 1906 to 43,018 cwts., as against 34,119 cwts. in 1905. In spite of the importation of carnauba vegetable wax having risen about 25%, the price continued to rise, from which it is inferred that this wax is indispensable for certain manufactures. The imports of carnauba vegetable wax were 32,607 cwts. The consumption of Japanese vegetable wax was about the same as in 1905, but prices became steadier.

Resin.—The fluctuations in the price of resin were not so great as in the previous year, but prices were very unsteady, and business was consequently impaired. In 1906 323,952 barrels of American and 22,284 barrels of French resin were imported, against 328,598 barrels of American and 18,774 of French resin in 1905.

Turpentine.—The imports of turpentine were rather less than in 1905, but the sales were larger. The imports of American and French (including Spanish, etc.) were 48,878 barrels and 15,500 barrels respectively, against 55,502 and 16,672 respectively in 1905.

Palm Kernels.—The amount of palm kernels imported in 1906, viz., 156,000 metric tons, was again insufficient to supply the demand of the German palm oil factories. Prices obtained a level hitherto not reached.

Dye-woods.—Business in dye-woods is said to have been better than in the previous year, owing to a general upward movement in prices such as has not been experienced for several years.

Digitized by Google

The total imports to Hamburg of the chief sorts of dye-woods in 1906 and the preceding year were respectively as follows:—

	Cwts. 1905.		Cwts. 1906.
Campeachy logwood	114,000	..	157,150
Jamaica and Domingo logwood	98,200	..	199,350
Yellow wood	39,300	..	35,350
Red wood	14,700	..	17,680

Indigo.—In all classes of East Indian indigo less business was done than in the previous year, because the consumption had fallen off owing to the failure of the Indian crop the year before and to the consequent rise in prices. Guatemala indigo found a ready sale, and a large business was done in Java indigo, for this quality affords relatively the cheapest dye.

Quebracho Wood.—After the new German customs tariff had come into force (on March 1, 1906) business in quebracho wood and in Argentine quebracho extract declined, and prices reached an unusually low level; but it is confidently anticipated that better values will be realised in 1907. The imports of quebracho wood and Argentine quebracho extract amounted in 1906 to 99,000 tons and 14,320 tons, against 110,000 tons and 12,000 tons in 1905 respectively.

Myrabolans.—The new duty imposed upon myrabolans is considered to be relatively excessive, in view of the small value of this product, and consequently prices paid (under bond) fell considerably. The total imports of myrabolans amounted to 14,300 tons, against 15,000 tons in 1905.

Nitrate of Soda.—Chili saltpetre has not for many years obtained such prices as in 1906. The event of chief importance was the renewal for three years of the so-called ring of producers, the object of which is to determine the maximum exports for the year in accordance with the anticipated demand. Contracts were made for monthly deliveries f.o.b. up to 1911 and 1912. Prices at Hamburg averaged high and were subject to unusually violent fluctuations. The total imports amounted in 1906 to 564,000 tons, or 42% of the total exports from South America, against 510,000 tons in 1905.

Phosphates.—Throughout the year the prices paid for all classes of phosphates continued to improve. A brisk business was done and contracts were made extending over a number of years. The total imports to Hamburg and the neighbouring port of Harburg rose from 195,925 tons in 1905 to 215,874 tons in 1906, of which 148,676 tons consisted of Florida rock and 40,430 tons of Algerian phosphates. The price of Florida phosphates rose 33%, and of other sorts 20 to 30%.

Bones and Bone Flour.—The home supply of bones appears to have been ample for the requirements of agriculture in Germany, for only 1,350 tons of bones were imported against 4,097 tons in 1905; but the imports of bone flour rose from 7,323 tons in 1905 to 9,028 tons in 1906, of which 6,428 tons came from India.

Sulphate of Ammonia.—The production in Germany of sulphate of ammonia amounted to about 200,000 tons, which was an increase of about 25% over the previous year's output, and consequently the importation both in Germany and at Hamburg fell off considerably. The imports to Hamburg amounted to 7,646 tons, against 11,602 tons in 1905. The exports of this substance from the United Kingdom to Germany amounted to 17,545 tons, against 29,009 tons in 1905.

The Associated Chambers of Commerce.—The autumnal meeting of the Associated Chambers of Commerce will be held in Liverpool, on September 18 and 19.

The Rise in the Bank Rate.—The *Investors' Guardian* says:—"The rise in the bank rate was almost a foregone conclusion, and we marvel to see it stated that the rise both surprised and puzzled the Stock Exchange. We cannot believe that the Exchange was surprised, though in an uncertain mood it may profess to have been puzzled that the favourable bank return should accompany a rise in the discount rate. The storm signals had been up for some days, and the Bank, with its official minimum rate at 4%, had only been doing business at 4½%. The position was complicated by the fact that during the week the Bank gained in imported gold and by the return of coin and notes from circulation, and the decision of the Court of the Bank was late in appearing, from which it is generally deduced that the discussion was lengthy. With the usual American demand looming ahead, with Wall-street ready for firework displays in season and out of season, and with a German bank lately taking gold from the bullion market for the Continent, one feels reassured, rather than otherwise, now that the official minimum rate has been advanced."

PATENTS AND DESIGNS BILL, 1907.

THE following circular has been issued to all Members of the House of Commons by the Council of the Association of British Patentees:—

The Patents and Designs Bill was introduced as a non-party measure which appealed to the patriotic instincts of every section of the House of Commons. It purported to satisfy the desire for the abolition of various provisions in our patent law which notoriously have lent themselves to abuse by foreign manufacturers, to the detriment of British industries. Thus the Bill has easily reached the stage of Report, and bids fair to be carried without any serious opposition to its main proposals.

But whilst the Bill admittedly cuts into the very roots of our patent law, the great body of British inventors and patentees were neither consulted nor remembered when the legislature was invited to alter fundamentally the law affecting their property, and incidentally to prejudice gravely the commercial value of every existing and future British patent. In order to give a corporate expression to the objections which the Bill finds in the view of every British inventor and manufacturer working under the protection of British Letters Patent, the "Association of British Patentees" submits the following considerations. In now addressing the Members of both Houses of Parliament on the grave dangers threatened by the Bill to every patentee, the Association ventures to hope that the Bill will not be passed without such modifications as may tend to avoid the proposed most serious disregard to the established rights of inventorship and the interest of the community at large in their recognition and protection.

The unusually large number of amendments which have been set down promise to meet many of the merely technical objections to the Bill in its present form. The Association of British Patentees takes objection to the following principles embodied in the Bill.

Clause 6.—(1.) A sealed patent is no longer to be a final grant. The comptroller of patents will obtain the power to require the amendment of a specification even long after the grant has been completed and the sealed patent has become the foundation of commercial enterprise.

Clause 7.—(2.) The grant of any patent may be refused by the comptroller *proprio motu*, on the ground of anticipation, and the applicant will no longer be entitled to test the validity of an unopposed patent in the courts of law.

Clause 10.—(3.) Any person may harass applicants for patents oppositions even where he cannot prove the remotest interest in the subject matter.

Clauses 10 and 14.—(4.) The comptroller may revoke any patent on any ground available for opposition to the grant and on the application of any member of the public, and the patentee will have no right to appeal beyond one single judge of the High Court.

Clause 15.—(5.) The comptroller may revoke any patent if the patentee does not happen to attain full commercial success within the first four years; for the patent then becomes revocable, if it can be shown that the invention is worked exclusively or mainly outside the United Kingdom. The comptroller is to be allowed a limited discretion, but the Bill provides no definite safeguards for British patentees who are prevented from meeting foreign competition within the first four years.

Clause 16.—(6.) One judge may revoke any patent if the patentee insists on working his patent to the exclusion of his particular trade competitors and the latter can make out that their industry is "unfairly prejudiced" thereby; of course they can maintain this in every case where a patent is of any real value as a weapon of commercial competition. In the alternative, any trade competitor may demand a compulsory licence and thus compete with the inventor in exploiting the patent.

Clause 27.—There will be no appeal against the decision of the judge.

Clause 23.—(7.) Destruction of common law rights. The existing law already gives any party to a contract relief against conditions in restraint of trade, where the special circumstances of the case show such conditions to be unreasonable. The Bill will place patentees as a class under new disabilities which the legislature and the judges have refused to apply to any other class, except, perhaps, to bookmakers and moneylenders. For no patentee can make it a condition of using his patent that any other patent of his shall be used or even the most trifling article obtained from him, apart from the precisely limited exceptions allowed by the Bill.

Digitized by Google

This itself is an intolerable interference with the freedom of contract, but the commercial value of patents will suffer indifferently to a still greater extent, for clause 23 will have the effect of forbidding any person selling a patented article or even any article in the production of which a patent has been employed at any stage, to stipulate in so selling that the buyer shall purchase any other article, whether patented or unpatented. Any such condition will be null and void, except in the two cases precisely circumscribed in the Bill.

Undoubtedly the entire community will find every dealing of daily commercial life endangered by this clause, but the patentee is also threatened with the loss of his patent, should any contract made by him be found to impose a condition of the kind described.

Not content with introducing an unwarrantable interference with the common law right of every British citizen to contract to the best of his judgment, the clause 23 will re-open a large number of existing contracts now in force, will cancel numerous valuable rights acquired in good faith and in reliance on the laws of the country, and will constitute an unprecedented destruction of vested interests. The grievance suffered by those affected will not be cured by such compensation as may be awarded by an arbitrator for cancelling the contracts, since pecuniary compensation within the limits of an arbitrator's discretion may, and often must, prove an entirely inadequate, if not illusory, remedy.

Clause 27.—(8.) There will be no right of appeal against the decision of the judge who may grant a compulsory licence or even refuse the grant of or revoke a patent. Patentees as a class are deprived of that right of appeal to the higher courts which is denied to no other litigant within the realm. On the other hand, the unsuccessful applicant for revocation will be free to take alternative proceedings ensuring to him the fullest right of appeal to the higher court.

Clause 24.—(9.) The Bill deliberately invites the infringement of patents by enacting that inadequate working by the patentee, the refusal of licences to trade competitors, or conditions which may be considered in restraint of trade, shall be a good defence in any action for infringement.

Clause 47.—(10.) The Bill is retrospective, and every patent granted, with every now existing contract concerning a patent, is subject to the hazards and disabilities introduced by the proposed measure.

The Association of British Patentees is convinced that the originators of the Bill were not aware that their measure must imperil the rights of every inventor, and those of every British manufacturer relying on the proprietary value of a patent, and venture to appeal, even at this late hour, to the judgment of those with whom the responsibility for the final form of the Bill now remains. For the Bill, in its present shape, constitutes one of the gravest dangers with which it would be possible to confront any British industry interested in the development of inventions and the protection of patent rights.

The subject here dealt with is of the utmost importance for the national welfare. Industrial progress, the advancement of trade and the economic efficiency of the nation are intimately bound up with the due reward of research and enterprise, and patents are the recognised and economically soundest and surest means to that end, and therefore the interference with patent rights contemplated by this Bill is a grave menace to British interests.

Continental Notes.

IN the *Chemiker-Zeitung* for July 31 and August 3, F. Wald discusses whether the stoechiometrical laws are comprehensible without the atomic hypothesis. His reasons for wishing to do without this fundamental theory are not easy to follow, and he himself complains that his papers in the *Zeitschrift für Physikalische Chemie* have attracted no attention, although that journal circulates among a public well up in mathematics.

The issue of July 31 also contains a paper by I. Schindelmeiser, on d-phellandrene in the oil of the *abies sibirica*, and another by S. Kohn, on the supervision of absorption towers. The latter is a theoretical paper, dealing mostly with methods of calculating the quantity of sulphurous acid that should be absorbed in successive towers at the end of a lead-chamber system.

H. Bollenbach describes a method for the determination of chromium by means of potassium permanganate. He has found that in hot acid solution chromic salts are quantitatively oxidised by permanganate to chromic acid. Full directions are given for carrying out the determination, and also a number of results, which show that a high degree of accuracy can be attained.

In the issue of August 3 is a paper by H. Kinder, on the metallography of alloys of iron and carbon. He briefly describes the modern views as to the compounds and mixtures that are present in ordinary irons and steels, and illustrates his remarks with diagrams and reproductions of microphotographs. The constituents that are considered are the three allotropic modifications of pure iron, α β and γ-ferrite, the two modifications of carbon, graphite and amorphous temper-carbon, and finally the carbide, cementite, Fe_3C. Amongst the microphotographs are some of perlite, the eutectic mixture of ferrite and cementite; and martensite, a solution of cementite in ferrite, which is obtained by rapidly cooling the iron from a temperature above 900° C.

There is also a description of a new pattern of fan—the "double Blackman," for which the advantage is claimed that it drives the air in the centre, as well as it does at its circumference.

An announcement which appears in the *Chemische Industrie* for July 15, will perhaps be read with interest by English manufacturers. It is as follows:—"From a well-informed source we have received confidential communications as to (1) the the extraction of sulphur in the State of Louisiana; (2) an opportunity of disposing of various chemicals in India; (3) addresses of importers and agents in Malaga." This confidential information will, of course, only be given to the members of the "Society for the Protection of the Chemical Industry of Germany."

In the same number there are extracts from the annual report of the factory inspector of Baden, and these deal largely with the disease known as "chloracne," which attacks workers in bleach works, whether the chlorine is produced by the electrolytic or other process. In electrolytic works the men who are affected are those who have to take out the exhausted cells, clean out the sludge, and replace them. In the Hargreaves process it is the men who have to clean out the towers in which the hydrochloric acid is absorbed in water, or in which the chlorine is driven out by means of sulphur dioxide. The most prominent symptom is the formation of small but painful swellings, sometimes accompanied by general inflammation of the skin. The exact cause of the trouble has not been established but it has been found that the effects can be prevented, or at any rate moderated, by cleanliness and care. By insisting on baths and special clothing it has been possible to greatly reduce the number of cases of disease. The action appears to be purely an external one, produced by some vapour or gas which directly attacks the skin, as is shown by the fact that it is principally the uncovered parts of the body which are affected, and especially where they are subjected to the friction of the clothes. Moreover, there are far more cases in the summer, when the clothing is lighter and is often worn open, than in the winter. There is, however, a general agreement that chlorine itself cannot be the cause of the trouble. Apparently a gaseous chlorinated product is formed, or at any rate a volatile one, and this is deposited with the sludge. There have been fewer cases since the precaution has been taken of allowing the plant to cool before opening it, and by washing it down well with water. Other measures of safety that should be adopted are that the workers should wear washable overalls fitting closely at the neck and ankles. Friction should be prevented by inserting wadding. The hands should be protected with impermeable gloves, and the head with a cap, the head and neck with a layer of vaseline. The face should not be touched during the work, and as soon as it is over the man should have a bath. The clothes should be washed before they are used again. Finally, the time during which the dangerous work is carried on should be cut as short as possible.

Two reports by Professors Jacobi and His respectively, upon a case of poisoning by the fumes of incompletely exploded dynamite, are given in the *Zeitschrift für das gesamte Schiess- und Sprengstoff-wesen*, for July 15. A partial misfire having occurred in a mine, a workman went up to the spot, and although he noticed a peculiar sweet taste in the air, continued to work there for some time, until he was compelled to go away by the sickly feeling experienced. He was taken ill, but nevertheless attempted to recommence work next day. He was obliged, however, to go into the hospital; he almost entirely lost his voice, and was eventually found to be permanently unfitted for work. The injury appears to have been caused by vaporised nitroglycerine. Recommendations are made for the better ventilation of mines and the prevention of workers from approaching the working face after a misfire until a considerable time has elapsed.

Analytical Notes.

THE CONSTITUTION OF AMMONIACAL LIQUORS.*

(*Continued from p.* 149.)

MR. LINDER'S MEMORANDUM.

THE methods employed in this laboratory for the analysis of ammoniacal liquors will be found in Annual Reports, 1903 (pp. 31-39) and 1905 (pp. 26-31). Procedure, generally, remains the same, but it is found better to replace the stoppered bottles employed for estimation of carbonic acid by flasks fitted with Bunsen rubber valves, to minimise the risk of fracture in the water bath, and enable procedure to correspond more closely with that approved by Fresenius. In addition to this and other minor changes, the method for estimation of thiocyanate, described in Report 1905, p. 28, has undergone complete revision. As there described, the thiocyanate was separated from the cold boiled liquor by means of copper sulphate and acid sulphite (at 30° C.), the cuprous thiocyanate being subsequently oxidised to cupric salt by evaporation to dryness with nitric acid and the copper determined volumetrically by means of potassium iodide and $\frac{N}{10}$ thiosulphate.

Precipitation in the cold† was adopted to obviate the contamination of the cuprous thiocyanate by copper sulphide—one of the decomposition products of copper thiosulphate at boiling temperature—and to minimise the separation of other insoluble copper compounds, which discolour the thiocyanate and vitiate results. The precautions adopted were generally successful in ensuring the separation of a cuprous thiocyanate of unquestioned purity, but, in certain exceptional cases, the procedure entirely failed in its object: the cuprous salt was brown in colour, and the weight of thiocyanate deduced by calculation from the copper obtained was far in excess of that reached by other and more reliable procedure. The method was therefore subjected during the present year to critical revision, and was finally replaced by that now to be described.‡

Estimation of Thiocyanate by Silver Nitrate Method.—This method is based upon the well-known fact that when cuprous thiocyanate is digested with excess of alkali, copper oxide and alkaline thiocyanate are formed; associated copper sulphide and other impurities are not affected by this treatment, and digestion with excess of alkali followed by filtration affords, therefore, a simple method of obtaining the thiocyanate in a condition suitable for exact titration with $\frac{N}{10}$ $AgNO_3$ after addition of nitric acid and iron alum. Caustic alkalies are usually employed to decompose the cuprous salt, but sodium carbonate¶ appears to be equally effective for this purpose if the amount of thiocyanate be small (under 0.1 gram HCyS); for larger amounts caustic alkali must be employed.

With coke oven liquors—which contain but little thiocyanate—the following procedure is found to give the best results; with gasworks liquors the amounts of the various reagents would be the readjustment, and the sodium carbonate should be replaced by caustic soda or potash.

A.—*Ferrocyanide absent.* If qualitative test (ferric chloride to acidified boiled liquor and warming) indicates that ferrocynaide is absent, add to 50 c.c. of the boiled liquor acid sulphite of soda followed by copper sulphate in distinct excess; boil from one to two minutes, filter, and wash the dark brown precipitate three times with boiling water (the filtrate should then remain colourless on addition of a drop of dilute ferrocyanide). Wash back the precipitate into the glass, add 25 c.c. of a 3% solution of sodium carbonate and boil for two minutes, filter (using the same paper§), wash three times with boiling water, cool, acidify with 5 c.c. of nitric acid free from oxides, and titrate on $\frac{N}{10}$ $AgNO_3$, 1 c.c. of saturated iron alum being added as indicator—

1 c.c. $\frac{N}{10}$ $AgNO_3$ = ·0076 grams NH_4CyS = ·0027 grams HCy.

The titration is made more exact if the silver nitrate be added in slight excess and the solution brought back with $\frac{N}{10}$ NH_4CyS. Care must be taken to ensure absence of chloride from all the solutions employed.

B.—*Ferrocyanide present.* To remove the ferrocyanide, add to the hot solution (90-95° C.) iron alum in sufficient excess to render the solution strongly red (ferric thiocyanate); after standing two minutes to allow the Prussian blue and hydrated oxide to separate, filter and proceed as in A. The solution need not be cooled before addition of the reducer and copper salt.

Special tests showed that no appreciable amount of thiocyanate is generated on boiling ammoniacal liquor containing cyanide and sulphide to remove those bodies. As regards errors due to solubility of cuprous thiocyanate in acid sulphite, and to the presence of sodium salts in the silver titration, the resultant effect of these disturbing factors is best determined by a "back test" on solution made up to contain given amounts of thiocyanate and thiosulphate—it should not exceed 0.5 milligram of thiocyanate calculated as hydrocyanic acid (HCy). Thus,

Organic matter absent:—

Solution A:—

Taken—Thiosulphate as sulphur	.0130 grams.
Thiocyanate, as hydrocyanic acid.	.0267 ,,
Found—(*a*) Thiocyanate	.0266 ,,

Equally satisfactory results were obtained in the same analysis when caustic potash was used in place of sodium carbonate:—

Thus:—

(*b*) Thiocyanate, as hydrocyanic acid found:—

(i) Cuprous thiocyanate extracted with 25 c.c. $\frac{N}{2}$ KHO at 100° C. .0267 gram.

(ii) Cuprous thiocyanate extracted with 25 c.c. $\frac{N}{2}$ KHO at 40° C. .0266 gram.

The alkali may be replaced by iron alum, which converts cuprous thiocyanate into copper sulphate and ferric thiocyanate and oxidises the copper sulphide:—

Thus:—

(*c*) Cuprous thiocyanate extracted by boiling thrice with 5 c.c. of saturated iron alum and decanting each time.. .. .. .0265 gram.

Solution B:—

Taken—Thiosulphate, as sulphur	.0640 gram.
Thiocyanate, as hydrocyanic acid	.0534 ,,

Found, Thiocyanate:—

(*a*) Cuprous salt digested 5 mins. at 40° C. with 50 c.c. $\frac{N}{2}$ KHO .. .. .. .0530 ,,

(*b*) Cuprous salt digested 20 mins. at 40° C. with 50 c.c. $\frac{N}{2}$ KHO .. .. .. .0529 ,,

Organic matter present:—

The following is cited in illustration of the result obtained with coke-oven liquors:—

Coke-oven liquor A:—

Thiocyanate found, calculated as hydrocyanic acid, grams per 100 c.c.:—

(*a*) Cuprous salt extracted with 25 c.c. $\frac{N}{2}$ Na_2CO_3 (1) .0175 (2) .0173 } mean .0174

(*b*) ,, ,, ,, ,, iron alum boiling .0174.

(*c*) Analysis by Mr. E. M. Fletcher, after one day's exposure to air (some thiocyanate formed by oxidation) .0189.

Coke-oven liquor B:—

Liquor highly charged with phenoloid bodies. No satisfactory precipitate could be obtained in the cold, the cuprous salt separating in a brown, semi-colloidal condition.

Thiocyanate found, as hydrocyanic acid, grams per 100 c.c.:

* From the 43rd Annual Report on Alkali, etc., Works, by the Chief Inspector.

† S. Dyson (*Jour. Soc. Chem. Ind.*, 1883, pp. 229-231) sought to remove organic matter and thiosulphate by evaporating the liquor on the water bath to dryness, heating in air oven, and extracting the residue with absolute alcohol. This procedure was shown in 1902 (Report 1902, p. 72) to lead to considerable loss of thiocyanate; indeed the method in Dyson's own hands yielded results which differed on the same liquor by as much as ·017 gram of ammonium thiocyanate per 100 cc. It is a matter for regret, therefore, that Dyson's procedure should continue to receive mention in technical handbooks as a standard method suitable for general use.

‡ Since the completion of this investigation, it has been ascertained that similar procedure has been independently worked out and applied in substantially the same way by other chemists for the estimation of thiocyanate in other liquors. The method in their hands has yielded results as trustworthy as those obtained in this laboratory, and one is justified, therefore, in recommending the procedure as entirely satisfactory in respect both of accuracy and despatch.

¶ The use of sodium carbonate for this purpose was suggested to me by Mr. J. W. Young as being more easily obtained free from chloride. Mr. Young further informs me that he has found potassium metasulphite ($K_2S_2O_5$) as sold in crystals for photographic use, an excellent reducer in place of acid sulphite of soda or potash.

§ This procedure ensures solution of the traces of cuprous thiocyanate remaining on the paper; it is simpler and more rapid than spreading the paper out on a clock glass and warming with alkali.

Digitized by Google

Cuprous salt extracted with 25 c.c. of 3% sodium carbonate—

(1) .0193.
(2) .0190.

Having thus established the accuracy of the Silver Nitrate method of estimating thiocyanate in presence of thiosulphate, it became of interest to compare the results obtained by this procedure with those afforded by the older method of oxidation of cuprous salt by nitric acid, p. 39 *ante*, with a view of determining the limits of accuracy of the latter.

Silver Nitrate and Nitric acid Methods compared :—

Coke-oven liquor C :—

A well-separated liquor; cuprous salt obtained by cold precipitation (Nitric Acid method), slightly discoloured :

Thiocyanate found, as hydrocyanic acid, grams per 100 c.c. :—

(*a*) Silver nitrate method	.022
(*b*) Nitric acid method	.024
Error due to separation of copper precipitate other than thiocyanate ..	+.002

Coke-oven liquor C :—

Liquor not well separated : cuprous salt, obtained by cold precipitation, dark brown :—

Thiocyanate found, as hydrocyanic acid, grams per 100 c.c. :—

(*a*) Silver nitrate method ..	(1) .0140 (2) .0138	mean .0139
(*b*) Nitric acid method	.0307	

The difference between the results yielded by the two methods (+ .0168 gram) is clearly due to contamination of the cuprous thiocyanate obtained in the cold with brown insoluble copper bodies of organic (or inorganic) origin, and not to any increased solubility of cuprous thiocyanate in the *hot* liquid, as analysis shows that it is immaterial whether the precipitation be made cold or hot so long as the cuprous thiocyanate is converted into alkaline thiocyanate and titrated on silver nitrate.

Thus :—

Thiocyanate by silver nitrate method as hydrocyanic acid, grams per 100 c.c. :—

(*a*) Precipitated cold	.0139
(*b*) Precipitated hot	.0139

These results prove conclusively that the silver nitrate method is the more reliable and accurate. It is also more speedy : analysis of a sample of boiled liquor for thiocyanate can by this method be completed within 35 minutes; by the Nitric acid method it would take 2½ to 3 hours.

Colorimetric methods for estimation of thiocyanate.—Pfeiffer has devised a colorimetric method for the analysis of ammoniacal liquors which is considered by Bertelsmann ("Die Technologie der Cyanverbindungen," p. 176, published in 1906) to give reliable and accurate results :—

Ten c.c. of the liquor are treated with 10 c.c. of a solution of 6% ferric chloride in 10% hydrochloric acid, filtered, thoroughly washed, and the filtrate diluted to 500 c.c. 100 c.c. of the dilute, red solution (= 2 c.c. of original liquor) are brought into a glass cylinder 3 cm. wide and about 22 cm. high; the colour is then matched with $\frac{N}{100}$ NH_4CyS solution in the usual way. If the depth of colour be too great for accurate comparison, less concentrated solutions must be employed.

Mr. J. W. Young, during the present year, has devised independently a colorimetric method for direct application to the boiled liquor. He has applied it for the analysis of coke-oven liquors with excellent results.

He writes :—

"Thiocyanic acid may in many cases be accurately determined in coke-oven liquors colorimetrically by boiling off all volatile compounds and diluting to 100 times the original volume. The colour struck by addition of nitric acid and iron alum is then matched in Nessler test glasses in the usual way against a weak standard solution of ammonium thiocyanate. A convenient depth of tint to work to is that afforded by 1 c.c. of $\frac{N}{1000}$ NH_4CyS in a 100 c.c. test glass. In cases where a determination of fixed ammonia has been made, the residue remaining in the distilling flask may be employed equally as well as freshly boiled liquor. Such a colour test can be made and remade in 15 minutes.

The following are typical examples :—

	By silver nitrate method.	By colour test.
No. 1. Coke-oven liquor ..	0.0149	0.0153
No. 2. „ „	0.0124	0.0129

Mr. Young's method has been tested in the laboratory against the Silver Nitrate method on three coke-oven liquors, with excellent results.

In cases where it is desirable to remove ferrocyanides, or to clarify the liquor, an addition of a few c.c. of saturated iron alum to the hot solution will be found effective. The excess of iron separates as hydrate and can readily be filtered off from the ferric thiocyanate together with Prussian blue and associated impurities. The thiocyanate can then be estimated colorimetrically in the filtrate in the way described above, after addition of nitric acid and iron alum (*see also* p. 47).

In closing these analytical notes, I desire to record my grateful thanks to Dr. Harold Colman and to Messrs. R. H. Clayton and G. W. F. Holroyd, for information concerning the methods employed by them for analysis of thiocyanate liquors by the silver nitrate method.

Composition of Saturator Gases.

The theoretical composition of the gaseous mixture leaving the saturator, in respect of the three constituent permanent gases CO_2, H_2S, and HCy, may be readily calculated from data afforded by an analysis of the liquor distilled, if we assume that the whole of the carbonic acid, sulphide, and cyanide (HCy) are evolved in the still and pass unchanged through the saturator. Experiment showed (*see* Report, 1903, p. 60, Leicester Corporation), (cyanide absent from liquor) that such an assumption was justified as regards the carbonic acid and sulphide.

Thus (residual nitrogen allowed for by calculation) :—

	In Saturator Gases, cold, per 100 vols.	
	CO_2 + N.	H_2S.
Calculated from average sample of liquor (3 days).	81.9	18.1
Found by Bunte burette (3 days) ..	81.6	18.4

At that date, however, no rapid and accurate method was available for estimation of volatile cyanide (HCy) in ammoniacal liquors, and the proportion of this constituent in the saturator gases was not considered. In 1904 and 1905 the accuracy of Feld's distillation method for estimation of hydrocyanic acid in liquors of every description was fully established (*see* Report, 1904, p. 28; 1905, p. 27), and it proved possible for the first time to arrive by calculation at the theoretical composition of the permanent gases CO_2, H_2S, and HCy evolved in distillation.

The results proved of unusual interest. It was found, generally, that the classification of liquors in respect of the proportion of HCy in the saturator gases correspond very closely with that based on the source of origin :—

	HCy in Saturator Gases per 100 Vols.
1. Coke-oven works, average of 9 liquors (1905)	5.5
„ „ average of 30 liquors (1906)	4.2
2. Gas works, average of 6 liquors (1905) ..	1.6
3. Iron works and shale works	Nil.

Such differences cannot be attributed to the fact that the liquors are of different strength, as the composition of the gases yielded on distillation is determined by the *relative*, not by the *absolute*, amounts of the carbonic acid, sulphide, and cyanide present in the liquor.

Differences of composition equally remarkable are apparent if one considers the figures for distribution of cyanogen compounds—thiocyanate, ferrocyanide, and cyanide (Table I., p. 46, Report 1905) and of sulphur compounds (*Ibid.*, Table H, p. 46). It was shown (*Ibid.*, pp. 30, 31) that the lower proportions of volatile cyanide and sulphide in gas-works liquors, compared with those in liquors from coke-oven sources must be attributed in great measure to the fact that ammoniacal liquors are peculiarly liable to be altered in character by contact with air—the oxidation products of volatile cyanide and sulphide of ammonia being the fixed ammonium salts—thiocyanate and thiosulphate. In gas works, where ample storage room is usually provided, conditions specially favour such reactions, while in coke-oven works the liquors are practically distilled as made.

Digitized by Google

In certain coke-oven works, where oven conditions were specially favourable for high yield of volatile cyanide, analysis showed that the liquor would yield saturator gases containing by theory as much as 17 to 18 parts by volume of hydrocyanic acid, per 100 volumes of permanent gases (Report 1905, Table B, p. 35). These figures were so striking as to be received with incredulity by certain manufacturers, who asked for confirmatory proof by direct analysis of the gases. Research was therefore undertaken, during the present year, to determine the extent, if any, to which sulphide and cyanide interact in the still under working conditions, and to devise methods for the direct analysis of the gases evolved. The results of this investigation are summarised below :—

Interaction of sulphide and cyanide when ammoniacal liquors are distilled. It is a well-known fact that ammonium polysulphide and ammonium cyanide interact in solution to form ammonium thiocyanate and ammonium sulphide—

$$(NH_4)_2S.S + NH_4Cy = (NH_4)_2S + NH_4CyS.$$

Polysulphide and cyanide are therefore mutually exclusive from the same liquor ; ammonium sulphide and cyanide, on the other hand, often coexist, and it becomes necessary, therefore, to determine whether these bodies react upon one another under distillation conditions—air excluded.* For this end, mixtures of sulphide and cyanide were distilled together, the evolved hydrocyanic acid absorbed in caustic soda, and its amount determined by titration on silver nitrate, after removal of the associated sulphide by carbonate of lead. Results proved conclusively that no appreciable formation of thiocyanate takes place, even when the liquor is boiled off into the open air, and further that the whole of the cyanide taken is recovered in the receiver, even when the evolved gases are made to pass through boiling sulphuric acid (13%), as in saturator working.

Thus :—

1. Action of H_2S on HCy in boiling solution (ammonia absent).

100 c.c. of solution containing the free acids distilled into half-normal caustic soda, a Liebig's condenser being interposed to condense the accompanying steam (as in Feld's method—Report 1905, p. 27)—

Taken H_2S	.0150 gram
HCy —	.0278 ,,
Recovered HCy	.0275 ,,

2. Action of $(NH_4)_2S$ on NH_4Cy in boiling solution.

100 c.c. of solution containing the freshly prepared ammonium salts distilled as above—

Taken ammonium sulphide as H_2S	.0150 gram
ammonium cyanide, as HCy ..	.0283 ..
Recovered ammonium cyanide, as HCy ..	.0289 ,,

3. $(NH_4)_2S$ and NH_4Cy boiled off together, and evolved gases passed through boiling 13% sulphuric acid.

This experiment was devised to imitate conditions existing in actual sulphate making. Two distillation flasks were employed in sequence, the first contained 100 c.c. of a solution of ammonium cyanide and sulphide of determined strength, the second 250 c.c. of 13% sulphuric acid. Connections were so arranged that the ammoniacal gases from No. 1 flask were delivered beneath the surface of the acid in No. 2, as in saturator working ; Liebeg's condenser and alkaline receiver were attached as above. In conducting an experiment, the acid in No. 2 flask was first boiled to expel air from the forward part of the apparatus, the contents of No. 1 flask were then distilled into the boiling acid for 20 to 25 minutes to completely expel the ammoniacal compounds and cyanide in the receiver determined as before.

At the end of the distillation thiocyanite was found to be absent from the residual liquor in No. 1 flask, proving that no interaction had occurred between ammonium cyanide and sulphide.

The whole of the cyanide taken was recovered in the receiver.

Thus :—

Taken $(NH_4)_2S$, as H_2S	.0150 gram
NH_4Cy, as HCy	.0283 ,,
Recovered NH_4Cy, ...	.0290 ,,

These results afforded strong presumptive evidence that when ammoniacal liquors are distilled the saturator gases would be found to contain CO_2, H_2S, and HCy in the proportions in which they exist in the liquor, the whole of the cyanide (HCy) thus being volatilised from the still.

(To be continued.)

* The formation of thiocyanate from interaction of cyanide and sulphide in liquors stored in limited contact with air was fully discussed in Report 1905 p. 31.

IMPORTS OF METALS AND MINERALS.

THE CONSTITUTION OF THE ATOM.

IN opening a discussion in the Mathematical and Physical Science Section of the British Association, at Leicester, Professor Rutherford said that it was only in the last decade that experimental methods had thrown light upon the interesting questions connected with the constitution of the atom. In a short historical summary he contrasted the Daltonian theory with the views held to-day, which regarded the chemical atom as the smallest unit that came into combination, but not the smallest unit that could exist. Chemical theory was not in any way disturbed by recent discussion, but rather strengthened by the experimental work that had been accomplished. Faraday had shown that the passage of electricity through solutions was due to the charge carried on ions. Helmholtz had carried the theory further, and his work was taken advantage of by Larmor, who developed the general theory of atomic constitution. The atom was an electrical structure possessed of positive and negative charged parts arranged within the structure. From the purely experimental side Professor J. J. Thomson showed that the cathode ray particles were in reality negatively charged particles travelling at very great speed, and that the particles consisted of very small quantities compared with the hydrogen atom, perhaps the one-thousandth part of the hydrogen atom. These small particles have been obtained in various ways, and each new experiment had confirmed their real existence. Kaufmann had provided additional confirmation of the fact that electricity was atomic in structure, and shown how the diameter of the small spheres over which there was a surface distribution of electricity might be calculated. The effective action of the electron was confined to small distances, perhaps ten times its diameter. The electron might be a state of strain in the ether, but its existence had been definitely proved by producing it in various ways, and must be regarded as a well-ascertained fact. Various attempts had been made to construct models of atoms. Lord Kelvin had suggested that the atom consisted of a number of spheres immersed in a sphere of positive electricity, and the suggestion had been developed by Professor Thomson, who regarded the atom as a sphere of positive electrification, and suggested the possibility that the electrons were arranged in rings, which were temporarily stable. In this view negative electricity was carried by the electron. Positive electricity might be regarded as a kind of cement holding the atom together. The electron was the active constituent in the atom. All attempts to show that the positive electricity was carried in the same way as the negative had failed. The positive electron could not be said to have been isolated.

Sir Oliver Lodge said he was prepared to champion the electric theory of matter, regarding it as a working hypothesis of the most valuable kind in providing a guide to experiment; and he trusted that it would long continue to hold the field and to stimulate the work of many explorers. He must regret that the theory had not won the full appreciation of Lord Kelvin, who had of late shown a tendency to destroy his own children. In any theory of matter it was necessary to explain mass or inertia, radiating power, instability, periodic weight, peculiarity of spectrum, and the Zeeman effect. Inertia could be explained electrically; an electric discharge was analogous to inertia and satisfactorily explained some difficulties. Radiation, again, was equally capable of explanation. An electric charge when accelerated must radiate, and that was the way in which ether could be thrown into waves. A compressible or dilatable ether was required, and herein lay a difficulty. Ether was not subject to gravitation, but was the vehicle for gravitation. Instability would arise if an atom were a revolving assemblage of corpuscles. If accelerated towards the centre there must be a loss of energy; there was a dissipative term in the equations, indicating that the electrons tended to become unstable. With regard to the positive charge, there was a difficulty. The positive electron might have no existence, but there must be a positive charge. Here there was grand opportunity for further investigation.

Sir W. Ramsay paid a tribute to the great physicists who had thrown so much light on these recondite matters, but as a chemist he was more interested in the proximate than the ultimate construction of the atom. Hydrogen was an element, but it might be more exact to regard it as an element connected with an electron, and he had a difficulty in disposing of this electron when forming a molecule. The behaviour of nickel in experiments which induced radio-activity on the surface offered some difficulties.

Mr. Soddy emphasised the distinction that had been drawn between speculations on the constitution of the atom and recent experiments achieved in radio-activity, and agreed with Sir W. Ramsay that the immediate interest of the chemist had reference to the proximate construction of the atom.

Professor Larmor pointed out that he had no theory to support, but he wished to assert the right of physicists to discuss the constitution of the atom. He wished to make it clear that radio-activity was not the only cause which had led to the discussion of these matters. Without the results of radio-activity the problem would be in the same position. Radio-activity only gave new material for support and confirmation. The science of electricity had developed, and the results, corroborated by optics and the connection between electricity and optics, had placed the molecular theory in its present position. Radio-activity had simply offered more facts to fit into an old theory. Helmholtz had emphasised modern views, but Faraday was the discoverer of the idea of the electron by his work on electrolysis. Lord Kelvin and Clerk Maxwell had given completeness to the ideas of Faraday, especially the latter, who formulated ideas which, perhaps, Lord Kelvin shrank from expressing. Maxwell had had the courage to lay the foundation of molecular and electrical science. He had wanted to postulate electrons, but could not fix them into his scheme. The difficulties felt to-day were felt by him. He knew that the electric theory accounted for both reflection and dispersion, but the method of propagation of molecules in fixed substances required further experiment before being ripe for treatment.

Lord Kelvin repeated his remarks of the previous day on the work done between different portions of matter when the distance between the particles was indefinitely small. Whatever new light had been thrown by radium and recent experiment on the origin of matter and the electric theory, the old foundations of science remained. He differed from the views of Professor J. J. Thomson in his theory of rings of electrons, and asserted that energy in the atom must be of the static type.

Sir William Ramsay, in a paper on the variability in the products resulting from changes in radium emanation, described a series of experiments suggested by the behaviour of radium in decomposing water. A small excess of hydrogen was produced in this case whose presence was difficult to explain. To pursue the inquiry copper compounds were substituted for water. In operating on copper sulphate the residue was found to give a spectrum of sodium, which was not surprising, but lithium was detected, the presence of which could not be explained. Further experiment was made, using pure electrolytic copper, and every care was taken to test for lithium, but after the experiment lithium was still found. Nitrate of copper was employed with all care, to avoid impurities, and after exposure to the emanation lithium was again detected. In another experiment the emanation was left out, and no lithium was detected. Again, when the emanation was dissolved in water and no copper salt used, the result was to give, not helium, but neon, in considerable quantities. The spectrum showed some lines in the green which might indicate new elements. The real difficulty was to explain why water gave neon and not helium. It might be suggested, as a working hypothesis, that the emanation was possessed of enormous energy, and according to the amount of energy used different products might be produced.

WILL.—The late Mr. Frederick Herbert Gossage, J.P., head of the firm of William Gossage and Sons, Ltd., soap makers, Widnes, left estate of the gross value of £720,041., including £709,396. net personalty.

THE SWEDISH BEET-SUGAR INDUSTRY.—The *Manchester Guardian* says:—"The report that the whole of the Swedish sugar works are to be combined in the form of a limited liability company serves to draw attention to the growth of this industry in Sweden. In 1889 there were six concerns interested in the manufacture of sugar, the total output being 6,750 tons, and the amount imported into the country 40,500 tons. At the present time there are 21 sugar works, the importation of sugar has practically ceased, and although Sweden only takes the seventh position amongst beet-sugar producing countries it is probable that she will shortly be in a position to enter the foreign markets. In 1900 the production was 81,300 tons; in 1901, 115,500 tons; 1902, 127,000 tons; 1903, 73,100 tons; 1904, 107,300 tons; 1905, 84,100 tons; 1906, 122,400 tons; for 1907 it is estimated at 157,700 tons. The fluctuations are due chiefly to variations in the harvest, and are observable in the statistics of all sugar-producing countries. The land in Central and Southern Sweden is admirably adapted for the cultivation of beetroot."

Parliamentary Jottings.

HOUSE OF COMMONS.

Wednesday, August 21.

LEAD POISONING.

In answer to Mr. Alden, Mr. Gladstone said that twelve cases of lead poisoning in the china and earthenware industry were reported to the Home Office in July. This was above the average monthly number of cases, but the total for the first seven months of the year was considerably below the number for the corresponding months of 1906. The whole question of lead poisoning, both in the Potteries and in other trades, was under his consideration.

BRITISH COMMERCIAL ATTACHES.

Mr. Runciman, replying to Mr. Lonsdale, said the recommendations of Sir Eldon Gorst and Mr. Llewellyn Smith, in their report on the system of British commercial attachés and commercial agents, had been adopted, and the new system came into force in July last.

EMPLOYERS' LIABILITY BILL.

The Employers' Liability (Insurance Companies) Bill, as amended by the Standing Committee, was next considered.

On an amendment moved by Mr. Claude Hay with the object of preventing "the springing up of mushroom insurance companies," Mr. Kearley (Parliamentary Secretary, Board of Trade), while quite sympathising with this design, pointed out that the amendment would have the effect of stifling mutual societies which were in no way suspect.

After some further discussion the amendment was withdrawn.

The report stage was concluded, and the Bill read a third time.

THE COMPANIES BILL.

On consideration of the Companies Bill as amended, Mr. Bottomley moved the following new clause:—"If any person or persons trade or carry on business under any name of title of which 'limited' is the last word, such person or persons shall, unless duly incorporated with limited liability, be liable to a penalty not exceeding £5. for every day upon which such name or title has been used."

Mr. Lloyd-George accepted the clause, and it was read a second time and added to the Bill.

Mr. Fell moved a new clause authorising a company which had carried on business for more than two years to issue new capital at a discount.—Mr. Hills seconded the motion.—Mr. Lloyd-George said that he could not agree to the proposal. There was very considerable opposition to it in the City, where financial authorities agreed it would be dangerous, as being likely to encourage gambling. If there was a bona-fide desire to save a company it could be done under the Act of 1900.—The clause was negatived without a division.

An amendment moved by Mr. Markham, requiring that where a company does not issue a prospectus each director shall sign the statement filed with the Registrar, was accepted by Mr. Lloyd-George and agreed to.

Mr. Fell proposed that the sum stated in the prospectus as the minimum amount on which the directors would proceed to allotment should require to be "not less than one quarter of the amount offered for subscription."

Mr. Lloyd-George did not think the amendment would afford any real security to investors, though it might delude them into the belief that they were protected by a statutory security. A prospectus had to state the minimum subscription upon which the directors would proceed to allotment, and if a purely nominal figure were given, people who invested were fools whom it was impossible to protect.—The amendment was negatived without a division.

On Clause 24 an amendment, moved by Mr. Robert Balfour, was accepted by Mr. Lloyd-George and inserted, providing that "any company which is a member of another company may, by minute of the directors, authorise any of its officials or any other person to act as its representative at any meeting of the latter company, and such representative shall be entitled to exercise the same functions on behalf of the company which he represents as if he had been an individual shareholder."

Mr. Hills moved the omission of Section 32, which gives power to the Court to grant relief to a director who may be personally liable for breach of duty if this has been caused by honest oversight, inadvertence, or error of judgment. He objected to any extension of the present law, which afforded a director sufficient immunity for innocent mistake. He reminded the House of the heavy losses suffered by shareholders through men who were wholly incompetent taking directorships and drawing considerable fees.

Mr. Lloyd-George pointed out that in many companies certain men were put on the board for special reasons, and because they had special technical knowledge of the business of the company. They confined their energies to one department, and it would be very unfair to make them liable for some financial blunder for which they were not responsible. He was not in favour of protecting directors who grossly neglected their duty, but he thought they ought to take care not to frighten away the best class of business men. He admitted that he did not quite like Sub-section 1 of the clause, because he thought the words were too wide. Honest directors would be amply protected by Sub-section 2, and if the House would assent to that course he was prepared to omit the first sub-section.—Mr. Lloyd-George's proposal was agreed to, and Sub-section 1 was struck out of the clause, and Sub-section 2 allowed to stand. This sub-section provides that relief may be granted in any proceeding against a director.

On Clause 37, which defined a "private company," an amendment by Mr. Lloyd-George was agreed to, providing that for the purposes of the Act the expression "private company" means a company which, by its articles, restricts the right to transfer its shares and limits the numbers of its members (exclusive of persons who are in the employment of the company) to fifty, and prohibits any invitation to the public to subscribe for any shares or debentures of the company.

An amendment by Mr. Rawlinson to the same clause, providing that wherever in the Companies Act a minimum of seven members is required, only two members shall be required in the case of a private company, was also accepted and agreed to.

The report stage was then concluded, and the Bill read a third time.

New Platinum Discoveries in Russia in Asia.—It is stated that platinum has been found in several new places in the Northern Urals, particularly in the neighbourhood of the Hasarieff and Schouvaloff Estates. These deposits are quite near the surface. The most striking find, according to *Torgovo Promysshlennaya Gazeta*, has been made near Artuisk, a district hitherto unknown to the either platiniferous or auriferous. The report also states that efforts are again being made on the Ekaterinburg market to raise the price of platinum.

Obituary.—The death took place recently of *Dr. John Clark* Ph. D., F.I.C., the President of the Society of Public Analysts. *The Analyst* says:—Dr. Clark was born in 1844, being the only son of John Clark, a well-known practitioner in mercantile law in the city of Glasgow. He received his education in the "humanities" at Glasgow University, and, having a taste for chemistry, became a pupil in the well-known laboratory of the late Dr. Penny. He subsequently proceeded to the University of Göttingen, where he worked with Fittig and Wöhler, gaining the degree of Doctor of Philosophy for a dissertation on amido-valerianic acid. He also studied for a session at Heidelberg under Bunsen, and afterwards worked in Paris for nine months in the laboratory of Professor Payen at the Conservatoire des Arts et Métiers. At the still early age of twenty-three he returned to Glasgow, where he was for three years senior assistant at the Andersonian College to his old teacher Penny, acting as his substitute during the illness which ended in Penny's death. In 1870 he joined his friends Mr. Tatlock and the late Dr. Wallace in forming the widely-known firm of Wallace, Tatlock, and Clark, who, in addition to their analytical practice, carried on a very successful private school of technical chemistry. For some years Dr. Clark also lectured on chemistry in the Medical School of the Royal Infirmary at Glasgow. In 1888 the original partnership was dissolved by the retirement from the firm of Mr. Tatlock, who established the separate practice which he still carries on in conjunction with Mr. R. T. Thomson; and the death of Dr. Wallace left Dr. Clark in sole charge of the laboratory of the original firm at 138, Bath-street, until his son and survivor, Mr. R. M. Clark, became qualified, a few years since, to join his father in partnership. Dr. Clark's contributions to chemical literature were many, being almost wholly directed to the practical advancement of analytical chemistry.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements Relating to the Treatment of Refractory Zinc-lead Ores P. C. C. Isherwood, The Oaks, High Road, Harrow. British Patent, 16,364 July 19, 1906

According to this invention the ores are treated with ammonium chloride or ammonium sulphate for the solution, when ammonium chloride is used, of the bulk of the zinc, lead and copper, and a proportion of the silver contained in them, or, when ammonium sulphate is used, for the solution of the bulk of zinc and copper and a trace of the lead, and for the subsequent precipitation thereof under conditions that do not involve the necessary use of any other reagent, and which permit of the regeneration of the ammonia employed as chloride or sulphate.

Improvements in or Relating to Ore Concentration. H. L. Sulman, 44, London Wall, London. British Patent, 19,944. September 17, 1906.

The object of this invention is to improve those processes in which different mineral particles are separated from one another by the differential action of a film or surface of liquid whereon certain particles may float on account of the surface tension while other particles do not float.

In British Patents No. 25,204 of 1904, No. 25,204A of 1904, No. 29,374 of 1904, and No. 5,260 of 1905 are described various processes and apparatus for the separation of different mineral particles from one another by exposing the particles to air and afterwards causing them to meet the edge or surface of water, when certain particles such as metallic sulphides, etc., float, and are separated from other particles such as gangue which sink, and a particular apparatus for carrying out such processes is described in Application No. 9,981 of 1906. This invention is applicable to processes of this general type. In the former two specifications referred to above it is pointed out that the adaptability of the liquid for the flotation process is capable of being modified by any chemical or physical agency which is known to modify the phenomena of surface tension or capillarity.

According to the present invention it has been found that in processes for separating particles which float upon a liquid surface owing to the surface tension from particles which do not float, the flotation power, *i.e.*, the readiness with which the mineral particles are caused to float, is increased by warming the liquid within certain limits. For example, in a process of separating different mineral particles from one another which consists in immersing these particles in a liquid such as slightly acidified water and in bringing the particles up through the surface, whereby certain particles are suspended on the surface and are separated from other particles which penetrate the surface, it is found that as the acidified water is warmed to a temperature of say 60° C. the readiness with which the mineral particles float gradually increases. On still further raising the temperature, the increase in flotation power is not in general so marked, and according to the nature of the minerals which are being treated the flotation power reaches a maximum which differs for different minerals and for solid particles of different characters. In certain cases, and notably with ores containing much iron pyrites, a temperature of 80° C. or more can be used with advantage.

In general, in the surface flotation processes cited above, the readiness to float certain particles, and the effectiveness of the separation, are improved by heating the liquid upon which the separation takes place, say, to a temperature between 35° and 90° C.

For different mixtures of solid particles the temperature at which the separation is most effective will vary, and a simple preliminary test can determine the proper limits of temperature for each particular case. In certain cases it may be advisable to vary the temperature of the liquid at different stages in the treatment of one ore, as, for example, where an ore or tailings is treated in a concentrating apparatus more than once, the liquid employed in the different operations may be heated to different temperatures.

Improvements in the Manufacture of Ammonia and Formic Acid from Cyanides. J. Y. Johnson, 47, Lincoln's Inn Fields, London. British Patent, 22,038. October 5, 1906.

Four hundred parts of barium cyanide are reduced to a coarse powder and introduced with 600 of water into a steam-jacketted autoclave provided with a stirring apparatus. Whilst stirring, the temperature is raised slowly to 150° C., and this temperature is maintained for about five hours until the pressure in the autoclave remains constant, thus showing that the saponification is complete. On opening the autoclave the ammonia, which is saturated with aqueous vapour but is otherwise pure, streams out and can be freed from water by cooling, and, if necessary, by passing through quicklime, and can then be compressed, or treated, or employed as desired. The residue remaining in the autoclave contains barium formate from which formic acid can be obtained in any desired manner.

The Manufacture of an Improved Dry Chlorinated Compound of Lime. G. W. Johnson, 47, Lincoln's Inn Fields, London. British Patent, 24,101. October 29 1906.

The patentee observes that it is well known that in the dry compound of lime and chlorine at present on the market, not more than from 80 to 90% of the chlorine contained therein are active, the remaining 20 to 10% being useless inert matter. All attempts, previous to this invention, to produce chlorinated compound of lime containing a much higher percentage of active chlorine have failed, as, in the usual processes, based on bringing dry slaked lime into contact with chlorine, the lime is not capable of taking up more than the amount of chlorine mentioned above.

According to the present invention, a dry chlorinated compound of lime is obtained, in an efficient and economical manner, the

Digitized by Google

compound having a contents of active chlorine of from 80 to 90%.

Instead of starting, as is usual, from dry slaked lime, milk of lime is taken, and through this, whilst being stirred, chlorine is passed until the lime is almost saturated with chlorine. The solution of chlorinated lime thus obtained is filtered, and then so evaporated that there is the least possible decomposition of the calcium hypochlorite. This can be effected, for instance, by concentrating the solution *in vacuo* at a low temperature, or (as the rate at which decomposition takes place is a function of temperature) by effecting the evaporation rapidly at a high temperature. The calcium hypochlorite is precipitated in a crystalline state and can be easily separated by suction and washing out.

Improvements in Gas Producers. C. L. Armstrong, Monticello Hotel, St. Louis, Missouri, U.S.A. British Patent, 24,666. November 3, 1906.

This invention consists in a down draught gas producer of the combination comprising a shell or generator, a header at each end thereof, a lid for the top of the producer, means for introducing the charge into the generator through the cover, an intra-mural water-circulating connection between the headers, a series of water-tubes opening into the bottom header and spanning the space between the inner walls thereof and serving as a grate for the charge, a steam (and air) injector leading from the top header and discharging into the space immediately above the surface of the charge, thereby driving the producer gas through the charge downward, the generator being provided with means for withdrawing the gas from a point below the grate. The specifications and drawings should be consulted.

Improvements in Rotary Kilns. W. R. Warren, 68, William Street, New York City, U.S.A. British Patent, 26,875. November 26, 1906.

The inventor claims :—(1.) In a rotary kiln having a double shield with outlet and discharge spout, the construction wherein one of the shields is supported or mounted on the kiln and the other shield is supported separate from the kiln with the discharge spout at or about the centre of the shields. (2.) A rotary kiln having an enlarged portion with a fuel intake, extended unbrokenly throughout a portion of the kiln and a reduced portion extended unbrokenly throughout the rest of the kiln, said enlarged portion having an outlet located above the bottom of the kiln, the peripheral portion of the latter being closed against outlet.

Improvements in Electric Furnaces. A. Reynolds, 11, Queen Victoria Street, London. British Patent, 26,981. November 27, 1906.

This invention relates to electric resistance furnaces of the kind in which the furnace lining or the crucible walls receive the whole or a part of their heat by conduction from an electrically heated resistance or resistances in contact therewith or separated therefrom only by a thermally conducting, although electrically insulating, inert material.

According to the present invention the heat is generated for the most part in a resistance of loose carbon ground to the necessary degree of fineness and packed between suitable retaining walls, and in order to obviate the destructive effects of excessive local temperatures due to "arcing" within the loose carbon resistance, and also to impart mechanical strength to the furnace the loose carbon resistances are enclosed within tubes or hollow bricks of solid carbon in suitable form such as plumbago, or are otherwise combined with plumbago bars or walls which while readily transmitting the heat generated in the loose carbon confine any excessive local generation of heat to the resistances themselves, thereby obviating the destructive action of such excessive temperatures on the crucible or the furnace lining or brasquing. In cases in which the loose carbon resistance is not entirely shrouded or enclosed by plumbago walls, it may if necessary be separated from the furnace lining or casing, or the crucible walls, by a thermally conducting brasquing or course of bricks made of carborundum or siloxicon or other suitable material which is inert to carbon and to the furnace lining or crucible at high temperatures.

The invention may be applied to the hearths of gas or coal fired reverberatory furnaces, Bessemer converters, muffles or ordinary crucible furnaces, and the construction of resistance above indicated forms not only a satisfactory electric heating agent but also serves to increase materially the mechanical strength of furnaces heated by loose carbon resistances, thereby obviating or reducing strains resulting from the stresses to which the crucible or the hearth is subjected by reason of the weight of the charge.

THE USE OF TAR FOR DUST PREVENTION.

We are informed by the Roads Improvement Association that the Judges' Committee appointed by the Association to carry out the competitions for the best tar-spreading machine and the best preparation of tar for road purposes, have made their awards as follows :—

Competition for the best Tar-Spreading Machine :—1st prize of 100 guineas and the Association's gold medal to Thomas Aitken, County Buildings, Cupar, Fife, for "Aitken's Patent Pneumatic Tar-Sprayer." Second prize of 50 guineas and the Association's silver medal to Tarspra, Ltd., 20, Victoria-street, London, S.W., for their 700 gallon "Tarspra" (Patent) Thornycroft Motor Van.

Competition for the best preparation of Tar for Road Purposes :—1st prize of the Ballymenagh Woollen Factory Company's 100 guineas trophy, and the Association's gold medal, to R. S. Clare and Co., Ltd., Stanhope-street, Liverpool, for "Clare's Patent Tar Compo."

These tests were carried out on May 22, 23, 24, and 27 last, on certain roads in Middlesex and Berkshire. Since these dates the roads have been kept under constant observation, and, durability being an important consideration, it has not been possible to make the awards until the present time.

A full report of the trials is now in course of preparation. It is proposed to divide it into two sections—one, the Judges' report on the respective merits of the various machines and preparations of tar entered for the competitions, and the other a full and comprehensive survey of the whole question of the use of tar for road purposes.

The cost of these trials was borne by the Royal Automobile Club and the Motor Union of Great Britain and Ireland. The Judges' Committee, in addition to members of the Council of the Roads Improvement Association and others, included eight leading engineers and road surveyors, appointed after consultation with the Incorporated Society of Municipal and County Engineers and the County Surveyors' Society.

The Growth of a Crystal.—At one of the evening lectures in connection with the Leicester meeting of the British Association on "The Growth of a Crystal," Professor Miers pointed out that a great many familiar things were actually made up wholly, or in part, of crystals, as, for example, minerals and precious stones, rocks, such as granite, basalt, and marble, and metals, such as iron and steel. The principles of crystallization that we studied here prevailed also in distant parts of space, for the crystalline structure of rocks and metals was to be seen in the meteorites that fell upon the earth from the sky; and the same principles had prevailed in remote past time, for many of the crystalline rocks were very ancient. The most wonderful feature of crystals was the manner in which they grew just as though they were living things. Two features deserved special attention. The first was the remarkable power crystals possessed of healing themselves when mutilated. If a growing crystal were removed from a solution, broken at one of its corners, and re-immersed in the solution, it would continue to grow, and as it grew would restore the missing part, and become once more a completely symmetrical figure. This power of continuing to grow was possessed by a crystal even after countless ages, so soon as it was immersed into the appropriate solution. In this sense the crystal was immortal, for it never lost its vitality, or power of growing. The other remarkable feature was the growth of crystals in over-saturated solutions. In solutions only slightly over-saturated, no spontaneous generation of crystals was possible. It was true that a solution only slightly over-saturated would often begin to crystallise, apparently spontaneously, when exposed to the air, but this was because there were minute crystal fragments of the dissolved substance floating about in the air which got into the solution with the dust and so inoculated the solution with crystal germs, just as the human body might be inoculated with disease by a disease germ. If these germs were kept out, the solution would not crystallize until it was very strongly over-saturated, and then, at a certain strength, it would suddenly begin to crystallize spontaneously and with great rapidity. In conclusion Professor Miers stated that so little had been done in the systematic watching of crystals as they grew, that interesting discoveries might be made by anyone who would take up their study, even without previous knowledge or experience.

THE "KÖSTER" AIR COMPRESSOR.—Amongst the orders recently received by Messrs. W. H. Bailey and Co., Ltd., Albion Works, Salford, for their "Köster" patent air compressors, is one for the South-Eastern and Chatham Railways, capable of dealing with 60,000 cubic feet of free air per hour, and another for the Daimler Motor Co., Ltd., Coventry, to deal with 14,000 cubic feet per hour.

CHESHIRE SALT EXPORTS.—The official statistics of the past month's Cheshire salt shipments report exports and coast shipments of 64,368 tons, being an increase on the corresponding month of last year of 15,589 tons. Exports to Asia were increased by 8,000 tons, to Australasia by 2,700 tons, and to Europe by nearly 2,000. There was a 4,000-ton reduction to British North America. The seven months' Cheshire salt trade this year is 24,000 tons below the corresponding period of 1906.

ARIZONA COPPER CO.—The profits for the half-year, including £11,508, brought forward, amounts to £259,687. After paying preference charges, the directors have resolved to pay an interim dividend of 2s. 3d., free of tax, on the preferred and deferred shares, leaving £76,433, to be carried forward.

THE INSTITUTE OF CHEMISTRY: EXAMINATIONS IN CHEMICAL TECHNOLOGY.—The next examinations in chemical technology will commence on Tuesday, October 29th, 1907. The examinations will be open only to Fellows, and to those Associates who have been registered as such for at least one year, who produce evidence of practical technological training. Fellows and Associates who desire to present themselves are required to send in their applications and fees not later than Tuesday, the 24th of September, 1907. All communications should be addressed to The Registrar, Institute of Chemistry, 30, Bloomsbury-square, London, W.C.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, July 30, 1907.

(Rate of Exchange, $4.87 = £1.)

Nitrate of soda remains in fair demand around $2.50. per 100 lbs. Sulphate of ammonia is inclined to dullness, at $2.05., as to make; white, for electrical, is in free supply, and sells as low as 5¼c. per lb. Lump sal ammoniac is steady, at 9½c. p lb. for good white seconds. Lump carbonate of ammonia is 7⅞c. to 8c. per lb. Bleaching powders are dull, at $1.20. to £1.30. Alkali and caustic soda are without change, at prices previously reported. Sulphate of copper is inclined to weakness, following the course of the metal, but the Syndicate price of 7d. is still maintained. White powdered arsenic is very dull; sales have been made at 7c. per lb. for prompt delivery, and futures are now offered at 6⅞c. to 7c. per lb. Canadian goods are coming on the market more freely. Red Saxony arsenic is 7½c. per lb. Calcined carbonate of potash, 80-85%, is 3¼c. to 3⅝c. per lb., and hydrated 4¼c. per lb. Caustic potash, 75%, is 4¼c. per lb. Chlorates are unchanged at convention prices. Bichromate of potash is 8⅜c. per lb., and soda, 7⅜c. per lb. Prussiate of soda is 9⅝c. to 10c. per lb. Prussiate of potash is dull, at 10c. per lb. Oxalic acid is offered a little more cheaply for future at 8c. per lb., and a steady business is being done at 8¼c. per lb.

TAR AND AMMONIA PRODUCTS.

Friday.

Benzols firm, with values given at 9d. for 90's, and 9d. for 50-90's. Crude Tar, 15s. 6d. to 20s. per ton Thames, 1¼d. to 1⅜d. per gallon delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, 26s. to 26s. 6d., f.o.b.; Gas Company, 29s.; East Coast, 25s. to 25s. 6d.; West Coast, 24s. to 24s. 6d., forward 2s. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 10½d. to 11d.; pure, 1s. 6d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5¾d.; 60%, 1s. 8d.; 75%, 1s. 11¼d. to 2s.; crystals, 39-40, 5¾d.; 34-35, 5¼d. Cresylic, 95%, 1s. 0½d. to 1s. 1d. Anthracene, 40 to 45%A, 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quiet. Nearest values are:—Beckton, £12.; Beckton terms, £11. 11s. 3d.; London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 16s. 3d. to £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined 11s. 9d.; Liverpool ordinary, 11s., refined 11s. 1½d. Official quotations:—Cargoes off coast or due, 11s. 1d.; ditto for prompt shipment, 11s. 5½d.

FERTILISER MATERIALS.

Friday.

There is no change to report in mineral phosphates, raisers of all grades being well sold ahead, and any business being done is at full prices.

East Indian bone meal for shipment attracts but little attention, £4. 17s. 6d. per ton, nett, c.i.f. terms Liverpool, would now be accepted for 4½ and 52% quality. On spot £5. 5s. to £5. 10s. per ton, according to quality, ex store, is required.

Nitrate of soda still remains quiet, but quotations are steady at 11s. 1¾d. to 11s. 4½d. per cwt., ex store, for ordinary and refined qualities respectively.

MISCELLANEOUS CHEMICAL MARKET.

Thursday.

The only important change to record during the past week is the large decline in value of sulphate of copper. Quotations to-day rule from £26. 10s. to £27., f.o.b. Liverpool, and the market has closed a little steadier. Caustic soda, ammonia alkali, and other allied products of the alkali trade remain unaltered. Saltcake rather quiet at 40s. per ton on rails. Recovered sulphur, bags, £4. 12s. 6d., f.o.r. Prices for chlorates and bichromates are steady, but there is not much inquiry. Prussiates continue easy, and the potash salt is offered on the spot at 5⅞d. per lb. Soda, 3⅞d. per lb. Supplies of white powdered arsenic are now coming forward more freely, and sales have been made for prompt at £31. 10s., Garston. American brown acetate of lime slightly weaker at £8. 7s. 6d. net, ex ship; grey unchanged at £12. 10s. per ton. Lead salts in better demand and prices are steady. Foreign white, £32., c.i.f.; brown, £26. 10s. per ton; nitrate, £35., delivered. Tin and zinc salts meet with more inquiry, but quotations are a shade lower. Nitrate of soda dull, at £11. to £11. 5s. Liverpool. Oxalic acid is now freely quoted for next year at 3⅛d. to 3¼d. per lb., but so far not much business has been concluded.

LIVERPOOL OIL AND COLOUR MARKET.

Thursday.

OILS.—Palm oil dull. Olive oil steady. Linseed oil also steady at 24s. 6d. to 25s. 3d. for Liverpool makes in export casks. Cottonseed oil in moderate demand at 31s. to 31s. 6d. for Liverpool refined in export barrels. Tallow, South American mutton, quoted at 34s., July-August shipment. Rosin steadily held at recent currencies. Turpentine steady, at 41s. 9d. per cwt. on spot. Petroleum firm, at 6½d. for Russian and Roumanian, and 7d. to 8d. for American refined oils. Petroleum spirit steady, at 1s. 0½d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

LIVERPOOL DRYSALTERIES.

Thursday.

Montreal potashes steady at 35s. per cwt. Pearl ash nominal. Cutch inactive. Gum arabic steady, with little offering. Castor oil quiet, at 3 9/16d. for good seconds Calcutta, 3½d. for second pressure French, and 3 11/16d. for first pressure French; Calcutta, for August-September shipment, 3⅝d. Gambier quiet, at 18s. 9d. to 19s. for block, and 18s. 6d. for June July; 18s. for July-August and August-September shipments; spot parcels of cubes, 28s. 6d. to 29s.; and 27s. 9d. per cwt. for August-September and September-October shipments. Shellac quiet, at 198s. to 200s. for fair T.N. orange on spot. American powdered starch, 10s. on spot, and 9s. 6d., c.i.f., for shipment; pearl, 9s. 6d. on spot, and 9s., c.i.f., for shipment. Glucose, American liquid, 43%, 10s. 4½d. on spot, and 8s., c.i.f., for shipment. Cream of tartar 98% foreign powder, 81s.; 95%, 79s. Tartaric acid: English on spot, 11¼d. to 11⅜d.; foreign, 11d. Citric acid: English 1s. 11½d.; foreign, 1s. 11d.

HULL PAINT, OIL, AND COLOUR REPORT.

Thursday.

OILS.—There have been practically no variations in prices of linseed and cottonseed oils upon the week; markets generally are unchanged. Amongst the principal imports here to date, as against the same time a year ago, are:—Wheat, 2,633,083 qrs., against 2,512,452 qrs.; flour, 125,660 cwts., against 241,143 cwts.; linseed, 502,178 qrs., against 336,551 qrs.; cottonseed, 125,413 tons Egyptian, against 107,061 tons, other kinds 121,897 tons, against 95,119 tons; rapeseed, 60,706 qrs., against 50,020 qrs.; oilcake, 17,725 tons, against 25,856 tons; hemp, 86,209 cwts., against 110,143 cwts.; olive oil, 3,474 tuns, against 2,917 tuns; tar, 3,794 barrels, against 7,103 barrels. Amongst the weekly imports are:—2,142 qrs. of castor seed from Bombay; lard, 7,260 cwts.; margarine, 2,866 cwts.; butter, 9,258 cwts.; sugar, 32,558 cwts.; glucose, 600 cwts.; hides, 794 cwts.; oilcake, 31 tons; colours, 2,740 packages; wool, 75,560 lbs. Exports:—Oil, 9,743 cwts.; colours, 3,016 packages; chemicals, 2,716 packages. Linseed oil has been dull and flat at the decline; spot naked, 21s. 1½d. per cwt.; September-December, 20s. 1½d.; January-April, 19s. 9d.; boiled and refined, £1. to £1. 10s. per ton extra. Exports during the week have been:—France 1 ton, Germany 2, Norway 7; total, 10 tons. Refined cotton oil has been quiet at the decline of 7s. 6d. per ton, near positions, and 2s. 6d. per ton distant; spot, 28s. 4½d.; November-April, 23s. 7½d. naked; casks £1., and barrels £1. 10s. per ton extra. Exports during the week:—12 tons France, 29 Germany, 11 Holland; total, 52 tons. Linseed closes dull, with imports of 27,285 qrs., with only small business passing at the decline from 6d. to 9d. per quarter. Cottonseed quiet, with prices about 2s. 6d. lower; August shipment for Hull is worth £8. 2s. 6d., imports 4,445 tons for week. Turpentine, 41s. 9d.; Russian, ditto, 20s. 6d.; Assyrian, 18s. Rosins unchanged. Castor and olive oils ditto.

CAKES.—The market for both linseed and cotton cakes has continued firm; 95% pure, £7. 5s. to £7. 10s.; Russians, £7. 5s.;

Digitized by Google

Americans, none; Canadians, £7. 10s. Oilcakes, £6. 5s.; cotton cakes, best, £5.; Bombay, £4. Rape cakes, £4. per ton.

PAINTS.—Unchanged.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

In this market a slightly improved feeling has been experienced during the week in sulphate of ammonia, of which for prompt f.o.b. Leith there has been an increased turnover at a steady £12. price, some sellers now looking for a fraction over. Forward delivery business has also revived, and several transactions are reported at £12. 2s. 6d. to £12. 5s. The fall in sulphate of copper has continued, following the tendency of prices in the metal. A fairly good feeling holds in general chemicals, forward delivery inquiry being notably more in evidence. Lead products have been easing off in quotations. The booking of burning oil contracts for the new season has been a large daily business, and continues. Creosote holds at 2¼d. naked, f.a.s. Glasgow, but the feeling is if anything stronger on the general market.

Chief prices current are:—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b. Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16., and boracic acid, £25., nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream, 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace), 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 1½d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 2⅜d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¾d.; ordinary sorts, 6½d. and 6¼d. (new season's contract prices), at Glasgow and other big centres; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42. and £40., less 2½% any port; saltcake, 40s. to 42s. 6d.; soda ash, £5. 10s. to £5. 15s., nett, Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d., prompt f.o.b. Leith; sulphate of copper, £29. 10s., less 5% Liverpool, prompt.

TYNE CHEMICAL REPORT.

THURSDAY.

Market continues very steady, and generally speaking there is a fair average demand. Soda crystals locally in good request, at £3. to £3. 2s. 6d. per ton, gross weights. Caustic soda, 70%, £9. 15s.; and 76-77%, £10. 10s. per ton. Bleaching powder, £5. to £5. 5s. per ton. Sulphur, scarce and firm, at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2 cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett; do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5/7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (saltcake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market continues very firm and all classes of Durham coals are scarce and firm, loading terms are long and the principal collieries have very little coal to offer for early delivery.

To-day's quotations:—Best Northumbrian steam, 16s. to 16s. 6d. per ton; second qualities, 15s. to 15s. 6d. per ton; Northumbrian small, 10s. 6d. to 11s. per ton; best gas coals, 15s. to 16s. per ton; Durham bunkers, 14s. to 15s. per ton; good coking coals, 14s. 6d. per ton; household coals, 16s. to 17s. 6d. per ton; foundry coke, 25s. per ton; gas coke, 20s. per ton.

New Companies.

Edmundian Copper Mining Co., Ltd.—Capital £135,000., in £1. shares. This company has been formed to acquire freehold and other farms, lands, buildings, mines, concessions, leases, mining, water and other rights, mineral and other properties in Africa or elsewhere, to adopt an agreement with the Consolidated African Copper Trust, Ltd., and to carry on the business of copper and general miners, prospectors, explorers, metallurgists, etc. No initial public issue. The first directors are H. D. Boyle, J. Seear and E. R. Tymms. Qualification, £250. Remuneration, £100. each per annum (chairman £150.) and 5% of the net profits, divided (maximum in any year £1,000.). Registered office, 8, Old Jewry, E.C.

Cumbrian Mining Co., Ltd.—Capital £25,000., in £1. shares. This company has been formed to acquire lands, mines, mineral and other properties and hereditaments in the U.K. or elsewhere, to adopt agreements (1) with F. Boehm and (2) with the British Mining and Metal Co., Ltd., and to carry on the business of miners, explorers, prospectors, concessionaires, quarry owners, etc. No initial public issue. The subscribers are to appoint the first directors. Remuneration (except managing director), £50. each per annum and a further £50. each in any year, payable out of the surplus remaining in any year when 10% dividend is paid.

Compound Metals Co., Ltd.—Capital £15,187. 10s., in 15,000 ordinary shares of £1. each and 3,750 deferred shares of 1s. each. This company has been formed to adopt an agreement with the British Aluminium Co. Ltd., and to carry on the business of manufacturers and workers of and dealers in metals, ores and minerals, alloys, metallic compounds, combinations of metals, engineers, founders, etc. No initial public issue. The holders of the original 1st debentures shall, so long as any of such debentures may be outstanding, be represented on the board in the proportion of one of three or two of four or more directors; subject as above; the subscribers are to appoint the first directors; qualification, £100.; remuneration, £100. each per annum and a share in the profits.

Hahnite (1907), Ltd.—Capital £60,000., in £1. shares. This company has been formed to acquire a certain invention for an improved oleaginous mixture for sprinkling on roads and the like, to develop and turn to account the same, and to adopt an agreement with Captain A. C. Way, D.S.O. Hahnite, Ltd., have consented to this registration. Minimum cash subscription £100. The first directors are G. H. Hopkinson, F. Rawson, C.M.G., Captain A. C. Way, D.S.O., and R. H. Hahn; qualification £100; remuneration, £100. each per annum (chairman £150.) and 5% of the dividend in excess of 10%, divided, provided that the remuneration of the chairman shall not exceed that of other directors by more than £50. (maximum in any year £2,000.). Registered office, 3 and 4, Gt. Winchester-street, E.C.

Society of Public Analysts and Other Analytical Chemists.—Registered with 350 members, each liable for £1. in the event of winding-up. This company has been formed to encourage, assist and extend the knowledge and study of analytical chemistry, adulteration, nature and composition of articles of food, drugs and commercial products generally. The word "Limited" is omitted from the title by licence of the Board of Trade. The management is vested in a Council. Registered office, 8, Duke-street, Aldgate, E.C.

Uneo Asbestos Lubricating Co., Ltd.—Capital £1,000., in £1. shares. This company has been formed to carry on the Agency in the United Kingdom for the sale of oils, asbestos, lubricants and other products of the General Lubricating Co., Philadelphia, Penn., and to adopt an agreement with the said company. No initial public issue. The first directors are J. B. Atherton and J. Atherton; qualification, 100 shares.

Wm. Bennett and Sons (Grimsby), Ltd.—Capital £20,000., in £10. shares. This company has been formed to acquire the business of manure and oil manufacturers carried on by Wm. Bennett and Sons, at Grimsby, to adopt an agreement with W. Bennett and G. L. Bennett. No initial public issue. The first directors are W. Bennett and G. L. Bennett (managing directors), W. S. Letten, G. S. Letten and L. A. Smith; qualification, 50 shares. Registered office, 256, Victoria-street, Grimsby.

LATE ADVERTISEMENT.

EXPERIENCED Tar Distiller and Sulphate of Ammonia maker, requires Situation; charge of small works preferred; best of references given.—"1,483," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**

Half-Yearly (26 numbers) ..... **6s. 6d.**

Quarterly (13 numbers) ..... **3s. 6d.**

Back Numbers of the Journal.—In future all back numbers will be charged at 6d. per copy, plus postage.

Communications for the Editor, if intended for insertion in the current week's issue, should reach the office not later than **Tuesday morning.**

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

CURRENT TOPICS.

FACTORIES AND WORKSHOPS INSPECTION.

THE most serious feature in the Annual Report of the Chief Inspector of Factories and Workshops' which was recently issued as a Blue Book (Cd. 3586), is the large increase in the number of accidents during 1906. In the year under review no less than 111,904 accidents were reported, this being an increase of 11.2%; in fatal accidents the rise was 5%. It must be remembered that these figures cover factories and workshops employing nearly 5,000,000 persons, but it is evident that the unusually large number of accidents is viewed with concern by the officials of the Department and by the Home Secretary.

The Chief Inspector reports that during the year there was a steady advance in exhaust ventilation for removal of dust and fumes, but that progress is often retarded by the neglect of occupiers to consult experts when installing the exhaust, or to keep it in good order when fitted. Examples of well-planned installations for the removal of injurious dust and fumes were published in book form during the year, and brought to the notice of occupiers. The final report of the Ventilation Committee will deal fully with the same subject.

Draft regulations for the manufacture of paints and colours were issued in July, 1906, followed by a revised draft in December; regulations have now been made by the Secretary of State, and came into force on the 1st February, 1907. The Commissioner's report on the inquiry into the objections to the Draft Regulations for the use of locomotives in factories, etc., held in November, 1905, was received in March, 1906; regulations were made by the Secretary of State in August, and with certain exceptions came into force on the 1st January, 1907. Further draft regulations for the generation and use of electricity were under consideration during the year, and have now been issued.

Circulars on the manufacture of nitro and amido-derivatives of benzene, and of explosives made with use of dinitrobenzol or dinitrotoluol, together with suggested regulations were issued during 1906 to occupiers concerned, and regulations are now under consideration.

The departmental memorandum on carbonic oxide poisoning was revised and re-issued, and another on dry cleaning was circulated in October.

The prohibition of the use of yellow phosphorus in the manufacture of lucifer matches was one of the subjects under discussion at the International Conference at Berne. France, Germany, Holland, Denmark, and Switzerland had already taken this step, and Italy has now decided to do so In Austria, Hungary, Belgium, Sweden, Norway, Spain, and Portugal, as in the United States and Japan, there is no prohibition. In the United Kingdom

Digitized by Google

reliance is placed upon control by Special Rules, and revision of these is under consideration.

The Chief Inspector reports that the recommendations which have been made, by circular, for precautions in the processes of tar-distilling, dry cleaning, and aniline black dyeing have generally resulted in improvements.

The number of cases in which legal proceedings were taken during the year was 4,155, against 3,946 in 1905; convictions resulted in 3,893 cases, and the average penalties were slightly higher than in the preceding year.

The volume contains the usual interesting detailed information and appendix. Several of the special reports, in particular that of the Medical Inspector, will be dealt with at length in our next issue.

BANKRUPTCIES IN 1906.

The official statistics of the Bankruptcy Department of the Board of Trade are never cheerful, but a summary of the figures must nevertheless be presented as the annual reports make their appearance. The report before us shows that during 1906 the cases of insolvency which either went into bankruptcy or were dealt with under deeds of arrangement were fewer, but the estimated loss to creditors was greater than in 1905. The cases dealt with in the report of the Inspector-General fall under two main divisions—those under the Bankruptcy Acts, 1883 and 1890 and those under the Deeds of Arrangement Act, 1887. The combined totals were:—8,077 cases, a decrease of 526; liabilities as estimated by debtors, £10,126,281., an increase of £451,811.; assets as estimated by debtors, £4,505,281., an increase of £114,699.; estimated loss to creditors, £7,926,211.,an increase of £261,123.

The number of receiving orders made in 1905 was the greatest during the period of ten years then ending. To the figures tabulated in the report have to be added 369 failures in Scotland, with liabilities £842,541. and assets £291,395.; and 287 failures and deeds in Ireland, with liabilities £306,452. and assets £95,576.

An interesting statement gives the number of failures in different trades or occupations. Of these grocery and provisions furnish the largest number, 971, though the total liabilities, £697,793., were not the largest for a single trade or occupation. Other businesses which contributed largely to the total were, building, 858, liabilities, £789,408.; beer, wine, and spirits, 438, £524,775.; metal 364, £431,918.; leather 320, £333,098.; farmers 318, £339,019.; drapers and haberdashers 314, £369,260.; tailors 225, £145,284.; bakers 225, £106,938.; butchers 200, £120,558. The largest total amount of liabilities for any trade was the £789,408. of builders.

"THE RELIGION OF RESEARCH."

At the recent British Pharmaceutical Conference, at Manchester, the President, Mr. Thomas Tyrer, emphasised with effect the vital importance of research work. A clever writer in our pharmaceutical contemporary, the *Chemist and Druggist*, playfully belabours Mr. Tyrer in some notes which make interesting reading, keeping in mind the recent strictures (already referred to in these columns) of the *Times* on "sensationalism" in science. "The dense world needs to be taught" (says the pharmaceutical writer) "how essential to its welfare are professors and pupils, and how important it is, therefore, that there should be an abundant provision of well-paid situations always ready for them. What might not Governments do with their millions of revenue if they could only be got to realise this importance? And are there not thousands of businesses being carried on in this country without the assistance of bachelors of science? Every now and then, as Mr. Tyrer says, things go wrong under most experienced hands. Clearly what is wanted is a youth fresh from college to explain things to the old man. Mr. Tyrer did not explicitly draw these conclusions from his really very interesting survey of the scientific activity which surrounds us, but it may fairly be presumed that they were at the back of his mind, as several expressions similar to the one just quoted suggest. Without admitting or disputing the inference, however, there can be no question about the vigour of present-day research. In every section of industry, in every department of study, toilers eager to add a new fact or fraction of a fact, or to elucidate some doubtful point, simply swarm. Nor is this energy limited to the pursuit of natural science only, or even pre-eminently. Antiquarian, historical, classical, philological, and other laborious researches are prosecuted with the same devotion that we recognise in chemistry or electrical science."

The writer points out that Mr. Tyrer's authorities furnish among them numerous suggestive definitions of or comments on research. Apparently, however, they were asked to deal with research in connection with the science of chemistry exclusively, for several of them give definitions inapplicable to any other kind. "Lord Kelvin, for example, replies that research is an endeavour to extend our knowledge of the properties of matter. This could not apply to historical investigations, for instance. Sir William Ramsay wittily compares research in science with speculation in business; an analogy which, if thought out, largely disposes of the stock plea for State aid for those engaged in it! . . . This tendency to speculation in business and to research in science is probably a growing one. Sir William Crookes, who has investigated many things in his time, hints at the curious law governing human efforts which seems to divide labour among various intellects. Not one person in twenty millions would have been attracted by the rare earths. Why was Crookes? It is a mystery, he says. Workers are apt to drift into their lines of study as some of them do to their results. But they have to have an investigating fibre in their brains, and this must be associated with industry and patience, or they would not become researchers at all. The dogmatic dictum attributed to Professor Armstrong, which, we are told, he once asserted to incredulous readers that 'all research ultimately leads to industrial results or ends in technology,' is not quite intelligible without the context. If it means that all research is valuable, readers will be well advised if they remain incredulous."

Our contemporary concludes:—"Research that has hindered progress has probably been more abundant in the history of learning than research which has aided progress. Dalton, says Mr. Tyrer, was a true researcher. He was so especially in the sense which Professor Wynne properly attaches to the term as 'covering the correlation of facts already known.' But it is not impossible that we may come to realise that Dalton's correlation of facts put us and kept us on the wrong scent for a century, just as Stahl's phlogiston theory had misled observers during the preceding 150 years. Nor need we go further than medicine and pharmacy to ascertain how scientific investigators can and do hinder progress. It is the correlators of facts who do the principal mischief. The briefest glance through the history of medicine suffices to show how little cause

Digitized by Google

there is to be thankful to these theorists for their services through some twenty centuries. Their antidotes and amulets, their hot and cold and moist and dry drugs, their humours and pneuma and archei, their doctrine of signatures and their universal elixirs, their vipers and human skulls and crabs' eyes and hartshorns, make up a pitiable record, and their authority hid from sight true principles of hygiene and immolated millions of victims to plagues and pestilences. Through all those ages the most useful work in medicine was done by the quacks, who did compound some valuable remedies, many of which are still with us. It is not permitted to suppose that any modern orthodox investigation can be other than wisely conceived and judiciously directed. But there are heretics who question the conclusions of such arch-researchers as Jenner and Pasteur. Imagine the possibility of the physicians of the future siding with the doubters of to-day. With what amusement or horror will posterity regard the now popular methods of treating one disease by the introduction of another!"

NITRATE OF SODA.

THE market remains deadly dull, with a weak tendency in all positions. Hamburg, in receipt of large supplies by steamers, is a seller of spot nitrate at the equivalent of 10s. 10½d. per cwt., and second-hand parcels are offering at about 11s. for spring delivery, but in the absence of buyers values are quite nominal. Owing to heavy arrivals and port stocks the premium on refined has practically disappeared. There are three large cargoes of ordinary at port of call, one of which has been awaiting orders for several weeks, and others are due for which destinations will with difficulty be found, all ports being already crowded. Prices have come down on the West Coast, producers being willing to accept under 9s. per quintal, f.o.b., compared with 9s. 4d. a year ago, when the market was very firm and rising in consequence of the Valparaiso earthquake. The imposing (in more senses than one) "Cuota Table" for the second year of the new combination, just received from Iquique, shows an initial allotment to 137 oficinas of 77,132,000 quintals, or 3,506,000 tons; the export cuota on the basis of 30% reduction is 49,433,065 quintals, exclusive of the share of eight large works not yet completed. Adding 7,013,859 quintals balance brought forward, the total allowed export comes out at 56,446,924 quintals or 2,565,769 tons, the world's consumption in the past combination year having been 1,580,349 tons. True, the scarcity of labour in Chili has so far prevented the shipment of the quantities officially sanctioned, but the raw material and the plant are ready to hand. In the meantime it must be admitted that the "regulation of supply and demand" on paper is sufficiently elastic!

German Chemicals.—A considerable advance has recently taken place in the shares of the large chemical companies, on the rumour of a "rapprochement," if not amalgamation, between the Badische-Elberfeld-Berlin Anilin and the Höchst-Leopold Casella groups. A contradiction is, however, now published by the Elberfeld Colour Works, which by the way are increasing their present share capital of £1,050,000. for the purpose of the contract entered into with their associates and a Franco-Norwegian banking syndicate for the production of artificial nitrate.

Potash Salts.—The following are the Potash Syndicate's deliveries in the seven months to July 31, compared with those in the corresponding period last year:—80% chloride of potash, 145,958 tons, against 141,207 tons; 90% sulphate of potash, 25,847 tons, against 26,107 tons; 48% muriate of potash, 18,482 tons, against 22,800 tons; 20% manurial potash salts, 43,104 tons, against 49,409 tons; 30% ditto, 16,944 tons, against 15,068 tons; 40% ditto, 94,885 tons, against 82,566 tons. Kainit and sylvinit, 1,074,417 tons, against 1,108,640 tons; carnallit and rock kieserit, 43,807 tons, against 46,341 tons; block kieserit, 15,246 tons, against 19,699 tons. The set-back is of bad augury in view of the prospective advent of new producers, and the position of the Syndicate leaves much to be desired, in spite of the recent patching up of differences.

GUM ARABIC IN EGYPT.

GUM arabic, which forms one of the more important minor exports in Egypt, is really the sap from a special kind of tree, which grows from 3 to 5 yards in height, whole forests of which are found in the Kordofan province, and also near Gedid, in the White Nile province. The natives are free to collect the gum, the only tax being a royalty levied at Omdurman. This royalty, which last year was about p. t. 12 (61 cents) a cantar (99 pounds), varies according to the market price of the gum, and is fixed annually by the Soudan government.

The seasons during which the trees yield their sap, according to the *Journal of the British Chamber of Commerce in Egypt*, in which these notes appeared, runs from December to May. Prior to gathering the "crop," the natives prepare the trees by slightly cutting the bark in numerous places. The sap then exudes, solidifies in the shape of large and small lumps, and is afterwards gathered by hand, such gathering being done before the rainy season commences.

There are two main classes of gum, *viz.*, ambery and bleached. In the latter case the gum is merely exposed to the strong action of the sun—generally in Omdurman—while in the former instance it is allowed to retain its natural amber colour.

At the present moment the Soudan article experiences great competition from the Senegal gum, while in certain trades dextrine replaces gum when the price of the latter is too high.

The *Journal* also observes that the selling price of gum arabic during the past six years shows a heavy decline. In 1901 the average price per kilogram was nearly 38 milliémes (17½ cents), while last year this figure dropped to 20 millémes (10 cents). The yield, too, in 1906 was the lowest since 1901.

THE NEW GERMAN CUSTOMS TARIFF.

THE last annual report of the Hamburg Chamber of Commerce contains the following observations as to difficulties attending the introduction of the new German customs tariff last year.

"The introduction of a new customs tariff, particularly when the same contains so many changes in its arrangements as the new German tariff which came into force on March 1, 1906, must necessarily be attended with great difficulties for all concerned; that is to say, more especially for the commercial classes and for the customs authorities. In the case of the new German tariff these difficulties have been greatly increased by its far reaching 'specialisation'; for it differentiates even between such articles as closely resemble each other in their nature, and between which in many instances no difference is made by the trading public; and it is so complicated that, in order to ensure its correct application, it has been necessary, in addition to the publication of an official list of dutiable goods (alphabetically arranged and provided with numerous notes), to issue also a volume of instructions, 300 pages in length, to the German customs officers, and these instructions have, in their turn, been supplemented by numerous periodically published official directions for the use of the customs authorities.

"The study and the attention required for carrying out all these instructions and directions in themselves alone make heavy demands upon the customs officials and upon the commercial classes concerned; more especially as many of the former customs regulations which were not directly affected by the introduction of the new tariff have now also been revised, a measure which might well have been postponed until some later time. What, however, is yet more serious, is the heavy amount of work entailed upon the German customs authorities by the numerous very minute investigations and analyses necessitated by the new tariff; and these are, moreover, the cause of very great delay in the customs clearance of many different kinds of goods, and the consequent accumulation of the latter in the custom-houses, thus creating a source of many difficulties for all concerned in their importation."

The Hamburg Chamber of Commerce is of opinion that the great difficulties with which the introduction of the new customs tariff has been attended were evidently not sufficiently foreseen and provided for by those who framed the tariff and who drew up the numerous instructions bearing upon its practical application, and the Chamber earnestly hopes that the German Government will seriously consider whether, in view of the experience now already gained, it may not be advisable to modify and simplify those instructions, and, if possible, also the customs tariff itself.

The reports as to the appearance of the olive trees at the date of the British Consul's report were not reassuring ; it is considered that the flower has sustained extensive damage.

THE BRAZILIAN WHALING INDUSTRY.

THE annual report of Mr. Consul O'Sullivan Beare (Bahia) contains some notes on the whaling industry.

Whaling is a pursuit which affords occupation to a large number of fishermen at Bahia during four months in every year. At the commencement of each cool season, whales regularly make their appearance from the south in the waters off the coast of this State. The first whales arrive usually about the middle of the month of May, and from that time onwards until the end of the month of September the waters along the coast, between Assu on the north to Cannavieras on the south, a distance of about 300 miles, literally swarm with whales, which have selected the strip of sea coast in question as their annual breeding ground. Frequently, during the season in question, whales enter the Bay of Bahia, and are there pursued and captured. Towards the end of the month of September the whales depart in a body, heading north, to be seen no more in these waters until the following season. What becomes of these whales from the time of their departure northwards during September until the time of their return out of the south during May of the following year is one of the mysteries of the ocean which still awaits solution.

The whales which visit the Bahia coast belong almost exclusively to the species *Balaenoptera musculus*, which are large of size on the whole ; some captured have measured over 70 feet in length.

The whaling season extends throughout the months of June, July, August, and the first two weeks of September. The Bahia men employ in their pursuit of the whales native-built double-ended open sailing boats of from 25 to 30 feet in length, each boat carrying a crew of from 8 to 12 hands. These boats prove serviceable enough for their purpose, if somewhat heavy, but they are entirely lacking in the beauty of model, the buoyancy and the handiness which characterise the incomparable whale boats of American build. The weapons employed by the Bahia whalers are the harpoon and the lance. The carcases of whales killed have all to be towed to the island of Itaparica, situated on the south side of the Bay of Bahia, where are located the trying-out works for boiling down the blubber. The men lose a considerable proportion of whales killed each season owing to their inability in many instances to tow the carcasses to Itaparica Island by reason of head winds or of heavy weather supervening after the whales have been secured.

The only portion of the *Balaenoptera musculus* reckoned to be of value is the oil, except indeed the flesh, of which the lower classes in Bahia are inordinately fond when they can procure it in a state of at least moderate freshness. The *Balaenoptera musculus* yields neither spermaceti nor whalebone. The yield of oil in the case of the species of whale in question is in proportion usually to the bulk of the carcass. An average yield is 700 gallons, but it is on record that some have yielded 1,200 gallons and upwards. The output of whale oil at Bahia varies considerably from season to season, the average being from 1,000 to 1,200 tons.

The whaling fishery here is not conducted on as large a scale or as vigorously as might be, and the methods adopted by the Bahia men for capturing the whales and for preparing the oil are of a very primitive nature. The industry is certainly susceptible of great development. Thus for example the employment of small steamers furnished with bomb guns, such as are used for killing the white whales off the Norwegian coasts, would ensure the killing of a much larger number of whales here than is practicable by the methods now in vogue, and the employment of such steamers would obviate the loss of carcases such as now occurs through inability on the part of the captors to tow them to the trying-out stations.

The British Consul suggests to British owners of whaling vessels the advisability of sending one of their ships on a trial cruise to these waters during a whaling season. So far as he can ascertain there exists no provision in the legal code of Brazil, whether Federal or State, which prohibits foreigners from fishing within territorial waters of the Republic. As regards a possible difficulty in connection with the matter of extraction of oil, that operation could be effected if necessary on board the whaling ship, as is done in the case of sperm whales.

Whale oil is graded at Bahia into two qualities, "refined" and "ordinary quality." During 1906 the price of ordinary quality oil averaged £14. per ton, c.f., and the price of refined oil averaged £22. 10s. per ton, c.f.

Refined whale oil as prepared at Bahia resembles cod-liver oil so closely in the attributes of colour, consistency, odour and taste as to be almost indistinguishable therefrom. The oil in question enjoys a high reputation locally for its medicinal properties and is preferred indeed to cod-liver oil. The point as to whether Bahia whale oil is really possessed of medicinal virtues akin to those of cod-liver oil assumes importance in view of the fact that refined whale oil is considerably lower in price than cod-liver oil. There are unfortunately only too many sufferers, consumptives especially, who would benefit from taking cod-liver oil regularly, but for whom the high price of that article is prohibitive. In the interests of such persons it is certainly worth determining as to whether or not the comparatively cheap whale oil constitutes an efficacious substitute for the more costly cod-liver oil.

Samples of "ordinary" and "refined" whale oil as prepared at Bahia can be inspected at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, E. C.

PATENT OFFICE FEES.—In a printed reply to Mr. Barnes, Mr. Lloyd-George says he is aware that the Patent Office fees have yielded a considerable profit of late years, but at the present time, whilst the office expenses are increasing and new duties are being thrown on the office by the Patents and Designs Bill, he can give no undertaking to reduce such fees. Mr. Lloyd-George adds that he does not believe that it would be to the interest of poor inventors to substitute for our present fees those chargeable in the United States, which would benefit the comparatively small number of successful inventors at the expense of the much larger number of unsuccessful inventors who can less afford to pay. He points out that the total fees in the United States amount to £7., and the patent remains in force for seventeen years. In the United Kingdom the fees up to the end of the fourth year amount to £5., and as over 65% of British patents are allowed to expire at the end of the fourth year the fees compare favourably with those of the United States. In regard to the additional £5. charged in the United Kingdom at the end of four years, it may safely be assumed that only such patents will be renewed as have met with some measure of success, in which case the fee is a comparatively unimportant matter.

Continental Notes.

IN the *Electrochemische Zeitschrift* for August there appears an account of an interview between M. U. Schoop and T. A. Edison, which is interesting as throwing light upon the methods of the American inventor. The conversation dealt largely with the iron-nickel accumulator, about which there has been so much discussion of late years, and which appears to have such a great future before it if only the inherent difficulties can be overcome. Edison was very open concerning the many failures which he has had both commercially and technically, and which would have been enough to discourage most inventors. For ten years he has worked at the solution of this problem in laboratories fitted out with every modern appliance, and assisted by a staff of forty trained electricians and chemists. He says that he has already spent a million dollars upon it. The iron electrodes especially presented many difficulties, as they showed most unaccountable variations in behaviour, and some rapidly lost their property of taking up the electricity, although others, prepared in the same way from the same raw material, were quite satisfactory. A works is now being erected for the manufacture of these new accumulators, and will be opened next June, the old factory at Glen Ridge River having been closed some months ago. Schoop states that it is a mistake to suppose that Edison has acquired great wealth with his many inventions (although he holds the world's record with 600 patents), for tremendous sums are spent on the laboratories, the advertisements conducted in the American manner, and patent lawsuits. Moreover, Edison is not so good a business man as an inventor. The obstinate perseverence with which he continues to work at the perfection of an invention with which he is not entirely satisfied has more than once failed to bring him an adequate financial return. To the magnetic separator for iron ores, for instance, he devoted eight years of continuous work without achieving commercial success, for although the separator works as Edison intended, it is much too expensive. The greater number of these separators have now been erected in the "Edison" cement factory, the product of which has great advantages over ordinary cement, and stood the test of the San Francisco earthquake very well, as the buildings constructed of "Edison" cement did not collapse. The cinematograph business is, however, going very well, and the same applies to the copper-zinc primary element. Of the buildings in connection with the laboratories one is devoted entirely to chemical research, and here Edison spends his time when he is not called away elsewhere. It cannot be denied that in many cases Edison was not the real inventor of the appliances with which his name is coupled; but in such instances we are indebted to Edison for putting into practice some fundamental idea, or for improving a very imperfect invention. This applies to the incandescent lamp, the cinematograph, and also the alkaline accumulator.

In the same issue there is some interesting information about the manufacture and use of artificial graphite, of which the International Acheson Graphite Co., in their large new works at Niagara Falls, made over five million tons in 1906. Besides being used for electrodes in electro-metallurgical and electro-mechanical operations, the material is applied in the manufacture of paints, for filling dry cells, for electrotypy, for lead pencils, and as a lubricant. In connection with the last application Acheson has recently made some very important discoveries, as he has found a means of obtaining graphite in a very fine state of division, suspended either in water or mineral oil. In either case the lubricating effect is a very high one. The water-graphite mixture is especially suitable for use in the cylinders of steam engines and other positions where there are objections to the use of oil. In the case of the oil lubricant the effect of the graphite is to make it possible to use a very light oil where formerly only a heavy one could be applied.

There is also in the same issue the final portion of a paper by Dr. Kraush, on developments in the electrical production of ozone. The paper consists mostly in reproductions of illustrations and particulars from patent specifications.

Another item that appears in the same number is the concluding portion of a translation of the preliminary report of the committee appointed by the Canadian Government to investigate the smelting of Canadian ores by electro-thermic methods. Instalments of this report have been appearing in the *Elektrochemische Zeitschrift* since April. The result of the experiments was favourable to the electrical process. The committee found that hematite can be treated by it as well as magnetite. From ores containing no manganese an iron can be produced containing only a few thousandths per cent. of sulphur, although the percentage of sulphur in the ore may be high. The silicon can be varied at will. Charcoal can be used instead of coke, and need not be briquetted with the ore. Ferro-nickel can be made from pyrrhotite containing nickel, and is of good quality, and practically free from sulphur. A 10,000 h.p. plant, which would be able to produce 120 tons of pig-iron a day, would cost 100,000 dollars, and the cost of production per ton would be 10.7 dollars.

Indian Notes.

RUBBER cultivation can be made to pay well in India. The Government plantations at Kulsi and Charduar, in Assam, are worked by the Forest Department. During the year, at Kulsi, the out-turn of rubber from 2,309 trees, occupying 88 acres, amounted to 4,120 lbs. The cost of tapping and harvesting was Rs.1,264.0, and the whole quantity was sold locally for Rs.12,428.0, the net profit being Rs. 11,164.0. The Charduar plantation, with 5,642 trees, occupying 388 acres, yielded 9,940 lbs. rubber. The expenditure on tapping was Rs.4,936., and the rubber was sold locally for Rs.29,827.0, or Rs.3.0. per lb. The net profit showed Rs.2.8 per lb. The Kulsi plantation has 160 acres, and Charduar 2,700 acres.

The working of the turpentine and colophony industry carried out by the Forest Department of the United Provinces shows that 105,891 trees tapped during the year yielded 287,444 seers of crude resin. The total collection and manufacture during the year gives:—Crude resin 339,920 seers, turpentine 10,664 gallons, and colophony 193,003 seers. The profits on the year's working were Rs.13,581; the values of the turpentine, colophony and crude resin having been taken at Rs.2.0. per gallon, Rs.5.0 per maund, and Rs.2.0. per maund respectively. With efficient and methodical organisation the business would yield a fair profit, and all that could be manufactured would find a ready sale.

During the last six years, owing to high prices, lac cultivators have reaped a fortune, and the amount is roughly computed at Rs.300,000,000. yearly. Yet there is room to double or treble this sum by putting lac seedlings on palas and other lac producing trees, which owing to ignorance are not at present used. There are four different qualities of lac, which are used for orange shellac, *viz.*, Baisakee, Cutkee, Jetee and Koosmy, and each derives its name from the Hindustani months in which it is collected. Besides these qualities there are the Assam, Rangoon, Siam, and Saigon lac, which are, however, too dark in colour, and are only used for garnet and dye. Manufacturers estimate that the Baisakee yields half the production of shellac, and the other half is made up of all the other qualities combined. The Baisakee crop just collected is estimated at 650,000 to 700,000 maunds, and the shellac made therefrom will be over 150,000 chests, a figure never yet seen by the oldest manufacturer of shellac in India.

Sugar-cane pests may be divided into insects and fungus pests, and for these remedies are sought. Insect pests are:—(1) The white ant or "dimak." The application of imperfectly fermented cattle dung particularly favours these. Copious irrigation, or the rains, are most effective. The native cultivator uses mustard cake, or a solution of asafœtida and common salt, to get rid of the pest. (2.) The sugar-cane borer; the larva burrows into the main stalk of the young plant. One pound of carbolic acid to 50 gallons of hot water is used, after which two pounds of slaked lime with one gallon of water is applied. (3.) Kari (black), dark spots on the surface of the leaves, when an insect appears and multiplies rapidly. The remedy is to burn the leaves. The fungus pests are (1) dark smut, which attacks the canes, and these not even cattle will touch. The remedy is burning. (2.) Red smut or "Lawahi," a most injurious pest. The leaves become pale as the disease progresses. There is no known remedy for this, and the whole affected crop is destroyed by fire. The area under sugar crops in India is 2,569,020 acres, and remedies for both pests, and also suitable fertilisers, are sought for.

THE STANDISH CHEMICAL CO.—It is announced that the Bone Works at Standish Lower Ground, Wigan, established in 1846 by Mr. Abraham Lloyd, have been purchased by a local firm, who have arranged to fit them up with the most modern plant for the manufacture of fine glues, gelatine, size, and manures. The new firm will be known as the Standish Chemical Co., and they expect to commence production in the course of a few weeks.

THE GEMAN CHEMICAL TRADE IN 1906.—III.*

By Consul-General Sir William Ward.

(*Continued from p.* 168.)

Lubeck.

THE trade in Finnish tar compared with the previous year shows a slight retrogression. Only in the late autumn, when the higher demands somewhat abated, were small consignments disposed of. In September and October Swedish imports arrived and found quick sale. The stock, imports, and exports in 1906 are shown below :—

	Barrels.	Half-barrels.
Stock on January 1	11,304 ..	7,767
Imports	19,594 ..	5,240
Exports	15,954 ..	5,651
Stock on December 31	15,004 ..	7,356

Pitch.—The trade in Finnish pitch was steady. The following figures show the stock, imports and exports in 1906 :—

	Barrels.	Half-barrels.
Stock on January 1	971 ..	189
Imports	1,494 ..	343
Exports	1,673 ..	313
Stock on December 31	792 ..	219

Portland cement.—The cement industry, in which several large firms are interested, has been in a most flourishing condition, so that the over-production of former years has all been sold at remunerative prices, which compensate largely for the heavy losses of 1904 and 1905.

Cement.—Not only has there been an enormous demand for cement for building purposes at home, but large quantities have been shipped to foreign countries, especially to the United States and Chile. Although prices in 1906 ruled 25% higher than in the previous year, the supply hardly equalled the demand. The results for the early part of 1907 promise well for the continued prosperity of the rest of the year. The San Francisco disaster accounts for a large number of orders.

Asphalt.—The half-dozen companies engaged in the asphalt trade can look back with satisfaction on the year's results, handsome dividends having been distributed. The United Limmer Norwohle Rock Asphalt Company has for the sixth year in succession paid 10%, although its capital was increased by one-third in the beginning of 1906, and the competition grows fiercer every year.

Potash.—The potash industry is represented by a large number of companies in the neighbourhood of Hanover, where discoveries of new deposits have been the order of the day for a long time. It is of interest to know that the first discovery was made on property belonging to the Prussian State when a search was being made for cooking salts. When first discovered it received a designation equivalent to "rubbish salts," which is still retained in German official reports. A syndicate was formed as far back as 1880 for the purpose of advertising the possibilities of the new discovery and for controlling the price. The creation of new companies has caused much trouble to the syndicate, which embraces at the present time no less than 36, while there are almost as many more outside the pale. Thus there is undoubtedly an increased production ahead.

As the Government is an important member of the syndicate, the object in view is to sell to German consumers, the Agrarian party, at far cheaper rates than the export price.

The chief outsider is the Sollstedt mine, which, with a view to obtaining the American market, has been underselling the syndicate. The value of the total output of crude potash salts rose from £1,482,000. in 1898 to about £4,600,000. in 1906. Speculation in potash shares has been very active, reaching its highest point in 1905. The nationalisation of the Hercynian mine early in 1896 gave rise to the idea that other mines might also be acquired by Government, and the prices improved, holders believing that Government would give good value for their properties. This, however, proved erroneous, so that at the end of 1906 prices were considerably lower than in the previous year.

* Special abstract of the British Consul-General's Annual Report on the Trade and Commerce of the Consular District of Hamburg for the year 1906.

FERRO-SILICON.

THE Board of Trade has received from the Home Office the following Memorandum (which is reproduced from the *Board of Trade Journal*), relative to the dangerous properties of ferro-silicon :—

"Professor Cronquist, of Stockholm, who was instructed to investigate the causes of the death of four of the passengers on board the Swedish steamship *Olaf Wijk*, confirms the view that their death must be attributed to the gases given off by ferro-silicon contained in the hold under the cabins.

"High-grade ferro-silicon, although it has been known to chemists for many years, has only recently been prepared on a large scale for technical purposes; *i.e.*, for adding to steel to increase the proportion of silicon; in steel rails about 0.5% of silicon is required in the finished steel, and in high silicon castings about 0.25%.

"It is made by heating together iron ore, quartz, coke and lime (as a flux) to an enormously high temperature in the electrical furnace; the coke reduces the quartz and ore to silicon and metal with the production of ferro-silicon containing up to 80% silicon. It is generally packed in iron drums or casks for export.

"Certain kinds of ferro-silicon seem to be decomposed, or rather disintegrated into powder, by the action of moist air; this apparently is not dependent on the proportion of silicon present, as specimens containing up to 80% silicon have been found to remain unchanged for weeks.

"Its poisonous properties can be simply explained by the fact that it is liable to evolve phosphoretted and arseniuretted hydrogen in contact with moisture. The iron ore and quartz often contain phosphates, which, in presence of carbon, and at the high temperature of the electrical furnace, would no doubt be converted into phosphides, combining with the lime to form calcium phosphide; in the same way any arsenic present would yield calcium arsenide. These would be decomposed in presence of water and would evolve phosphoretted and arseniuretted hydrogen, both of which possess powerful poisoning properties.

"The explosions that have occasionally occurred are more difficult to explain, and various theories have been put forward to explain them. These properties of ferro-silicon indicate that considerable danger is connected with its transport, not only to persons on the ship, but to dock labourers engaged in unloading it at docks. *Prima facie*, it seems that the presence of moisture is the cause of the accidents, and every effort should be made to ensure that the material is in a dry condition when packed, and that there is no possibility of moisture gaining access to the receptacles containing it."

CEMENT IN BRAZIL.

UNITED STATES CONSUL A. R. MORAWETZ reports as follows on the purchases of cement at Bahia :—

The imports of Portland cement at Bahia in 1905 were 20,000 barrels. There was an increased import in 1906 and should be a greater one in 1907. It is imported almost exclusively from Germany and Belgium in equal amounts, England and the United States supplying only a small fraction of the quantity consumed. The prices paid in Germany and Belgium are practically the same, although the cement from the latter country is considered a trifle better in quality. The first cost in both these countries is lower than in the United States, but the quality of American cement is better than either the German or Belgian product. The sale of an article here depends much more on the price than on the quality, and for this reason there is a larger quantity of German cement sold than of any other kind. It has the further advantage that freight rates are lower from Germany than from any other country, and also that its credit arrangements are more favourable than can be obtained from American manufacturers. There is no concrete used in the construction of buildings, and cement bricks are unknown here.

The selling price of German cement is from $3.36 to $3.66., and of Belgian from $3.97. to $4.27. per barrel, at the present rate of exchange of 3.275 milreis to the dollar. The duty at this rate is now $1.50. per barrel of 375 pounds net. Cement is always imported in barrels, which are not included in the weight when the appraisement for duty is made.

Exports of Argols from Italy.—Mr. Consul Cocoto, reporting on the trade of Lecce during 1906, states that the total exportation of argols by sea amounted to 1,236 tons, wine lees totalling 934 tons.

Analytical Notes.

THE CONSTITUTION OF AMMONIACAL LIQUORS.*

(*Continued from p.* 172.)

MR. LINDER'S MEMORANDUM.

ANALYSIS OF SATURATOR GASES (COLD AND HOT).

(*a*) *Cold Gases.*—A method for estimation of CO_2 and H_2S in cold saturator gases was described in Report 1903, p. 53:—100 c.c. of the gases were collected in a Bunte burette, caustic soda was then run in, and the contraction noted; unabsorbed gas was taken to be residual nitrogen; the sulphide was determined by titration with $\frac{N}{10}$ iodine, and the CO_2 obtained by difference.

For estimation of hydrocyanic acid a much larger volume has to be taken, as the amount of HCy in saturator gases is often less than 3% of the dry gases. Analysis is satisfactorily accomplished by means of a large stoppered cylinder of determined volume (1000-1100 c.c.), the gas obtained being absorbed by caustic alkali as before; H_2S and residual nitrogen are determined in independent sample by Bunte burette, and the CO_2 obtained by difference. A description of the apparatus and procedure will be found in Appendix, p. 52.

Analysis of the cylinder sample for cyanide was found to present exceptional difficulties:—Feld's method of distillation with lead nitrate proved to be inapplicable, as a considerable proportion (15 to 20%) of the cyanide becomes converted into thiocyanate by air necessarily introduced with the alkali; the total cyanogen contents is too small to be determined by the silver nitrate method described later. The difficulty was at length overcome by special procedure; this is fully described below.

(*b*) *Hot Gases.*—The problem of sampling hot gases for analysis was less easy of solution:—If the collecting vessel be kept cold, steam condenses freely, the constituent gases dissolve in the liquor in unequal proportion, and temperature and pressure measurements are thus rendered impossible. On the other hand, if the vessel be jacketed with steam or hot water, the weights of carbonate, sulphide, and cyanide obtained are insufficient for exact analysis. The difficulties were successfully overcome in the following manner: The hot gases were first allowed to stream through the cylinder to displace air and heat the walls to approximately flue temperature, the exit end was then closed, and the cylinder cooled by water. Rapid condensation was thus induced, a partial vacuum ensued, and a further volume of hot gases entered the cylinder, to be in turn condensed. As soon as a sufficient volume of liquor was collected, the cylinder was detached, caustic alkali run in, and undissolved gases absorbed in the usual way. The resulting solution contained carbonate, sulphide, and cyanide in a given, but unknown, volume of the hot gases. It only remained to determine the weights of these constituents present in an aliquot portion of the solution to obtain the data necessary for calculating the relation of the CO_2, H_2S, and HCy present in the sample of gas collected.

Estimation of Small Amounts of Cyanide in Gas Samples by Modified Polysulphide Method.—The use of polysulphide for the absorbtion and estimation of hydrocyanic acid is well known to technologists familiar with cyanogen recovery processes:—

The solution of thiocyanate obtained is freed from sulphide by boiling with lead carbonate, and the thiocyanate separated as cuprous salt, to be subsequently recovered as alkaline salt and titrated on silver nitrate.

In the present investigation the amount of thiocyanate available for analysis was, in general, too small for precipitation by copper sulphate way, and special procedure had to be devised to remove sulphide, organic matter, and thiosulphate from the test solution before titration with silver nitrate:—Sulphide was removed by neutralising the solution with sulphuric acid and boiling organic matter and thiosulphate by digestion at 90° to 95° C. with iron alum.

The specific action of this reagent has been investigated by Fordos and Gélis (Dammer's "Handbuch der Anorg. Chem." III. pp. 326 and 327; and Journ. Pharm. (1843) 4, 333). They show that thiosulphate is oxidised to tetrathionate, a body which has no injurious effect upon the silver titration, if the solution be cold and dilute. The excess of iron alum separates from solution as basic salt and can be filtered off if desired, but this is unnecessary.

The following procedure gives the best results:—

To 100 c.c. of solution add ammonium polysulphide in sufficient excess to colour it strongly yellow; raise to the boil and nearly neutralise with dilute sulphuric acid—approach of the end point is indicated by the sulphur separating white. Boil for 15 minutes to expel sulphuretted hydrogen, cool to 90° to 95° C., add 5 c.c. of saturated iron alum, and filter, after allowing the solution to stand a few minutes to complete the oxidation. Cool the filtrate, acidify with 5 c.c. of nitric acid, shake to dissolve hydrated oxide, and filter from residual sulphur. To the filtrate add 1 c.c. of iron alum and titrate on $\frac{N}{10}$ silver nitrate.

1 c.c. = .0027 gram HCyS, as HCy.

In general, the presence of organic bodies in the test solution causes the end point to be slightly yellow. It is more accurate, therefore, to add the silver in slight excess and bring back with $\frac{N}{10}$ NH_4CyS.

The following solutions are required:—

1. Normal ammonium polysulphide. Saturate 100 c.c. of N. ammonia with sulphuretted hydrogen and dilute with 100 c.c. of the same solution; add excess of flowers of sulphur, and digest for a week with occasional shaking. The supernatant liquid is withdrawn for use as required.

2. Nitric acid free from oxides. A litre of pure, concentrated acid is diluted with one-fourth of its volume of water, and boiled till white. Keep in the dark.

3. Saturated solution of iron alum.

Solutions throughout must be free from chloride.

Special experiments were made to test the procedure; the following conclusions were reached:—

1. *Action of iron alum upon thiosulphate.* Thiosulphate is rapidly oxidised to tetrathionate by iron alum at 80° to 90° C. Oxidation can never be completed so far as to yield a filtrate without action on iodine, thus:—

Thiosulphate taken, as sulphur .064 gram.
Thiosulphate found (after oxidation) .0006 gram.

2. *Action of iron alum upon ferric thiocyanate.* Thiocyanate is not affected by excess of iron alum, even in boiling solution. Thus:

Thiocyanate taken, as hydrocyanic acid .0054 gram.
Thiocyanate found, (1) boiled 3 mins. with 3 c.c. of iron alum .0054 gram.
" (2) boiled 6 mins. with 3 c.c. of iron alum .0054 gram.

3. *Removal of thiosulphate in presence of thiocyanate by iron alum.* Direct titration of thiocyanate in presence of thiosulphate invariably leads to high results, silver thiosulphate being formed and ultimately sulphide, even when nitric acid is present in large excess and the solution kept cold and dilute. Thus:—

Taken:—Thiosulphate, as sulphur .0032 gram.
Found:—(*a*) Thiocyanate, as hydrocyanic acid .. .. .. .0054 gram } difference + .0024.
Thiocyanate, as hydrocyanic acid .. .. .0078 gram }

The tetrathionate produced by treatment with iron alum has no effect on the silver titration if the necessary precautions are observed. Thus:—

Found, (*b*) thiocyanate, after removal of thiosulphate by iron alum, .0053 gram.

4. *Cyanide and thiosulphate do not react to form thiocyanate under the observed conditions.* Thus:—100 c.c. of a solution containing excess of ammonium cyanide, ammonium thiocyanate, sodium thiosulphate, and ammonia in slight excess were boiled for 15 to 20 minutes, 3 c.c. of saturated iron alum added, and the boiling continued for 5 minutes; the solution was then filtered, and thiocyanate determined by N $AgNO_3$.

Taken:—Thiosulphate, as sulphur .. .. .0200 gram.
Thiocyanate, as hydrocyanic acid .. .0054 "
Found:—Thiocyanate, as hydrocyanic acid .. .0054 "

The following example is typical of the results obtained in an actual estimation of hydrocyanic acid by this method, thiosulphate being present in the ammonium polysulphide used—Thus:—

Cyanide taken, as hydrocyanic acid .. .. .0097 gram.
" recovered as (thiocyanate, as hydrocyanic acid) .. .. .0094 "

The method is equally applicable for estimation of sulphur as polysulphide. For this purpose the cyanide must be in excess

*From the 43rd Annual Report on Alkali etc. Works, by the Chief Inspector.

Digitized by Google

from the start, to ensure complete reduction of $(NH_4)_2S.S_x$ to $(NH_4)_2S$; ammonium cyanide and sulphide are then boiled off, and the solution treated with iron alum exactly as described above.

1 c.c. $\frac{N}{10}$ $AgNO_3$ = .0032 gram sulphur as polysulphide (S_x).

Thus:—

In solution containing sulphide, thiosulphate, and polysulphide, sulphur found—

Sulphide by iodine titration	.0155
Thiosulphate ,, ,, ...	.0007
Polysulphide (S_x)	.0278
Total	.0440
Total sulphur by bromine oxidation ..	.0445

Mr. G. W. F. Holroyd, to whom the iron alum method of removing thiosulphate was communicated, informs me that he has found the procedure equally effective for removal of thiosulphates in the estimation of hydrocyanic acid in coal gas by polysulphide method and thiocyanate in trade liquors. He has compared the results so obtained with those yielded when the thiocyanate is estimated by precipitation as cuprous thiocyanate in boiling solution as described above (p. 40), and finds that a great saving of time is effected without any loss of accuracy. I am indebted to him for permission to quote the following:—

1. *Determination of Hydrocyanic Acid in Crude Coal Gas by the Polysulphide Method.*

	HCy found, Calculated as NH_4CyS. Lbs. per million c.ft. Expt. 1.	Expt. 2.
(*a*) By precipitation as cuprous thiocyanate ..	325	350
(*b*) By oxidation with iron alum	329	351

2. *Determination of Ammonium Thiocyanate in Liquor from Cyanide Scrubber.*

	Ammonium Thiocyanate NH_4CyS. Lbs per gallon. Expt. 1.	Expt. 2.	Expt. 3.
(*a*) By precipitation as cuprous thiocyanate	3.65	4.08	3.78
(*b*) By oxidation with iron alum ..	3.70	4.17	3.87

Mr. Holroyd uses 10 c.c. of saturated iron alum for oxidation, and allows the hot solution to stand four minutes before filtration from hydrated oxide.

Works Tests.

It has already been shown that study of the properties of ammoniacal solutions leads to the conclusion that on distillation such liquors yield the whole of the carbonic acid, sulphide, and cyanide together with ammonia and steam, and that when the mixed gases are passed into boiling dilute sulphuric acid ammonia is fixed as sulphate, the CO_2, H_2S, and HCy passing forward to the condensing system in proportions corresponding exactly with those existing in the liquor distilled. The correctness of this assumption has been established by careful analysis of saturator gases under working conditions. Great difficulty was experienced in obtaining the necessary data on account of the large volume of water vapour with which the hot gases are charged. On cooling, liquor separates which holds in solution carbonic acid, sulphuretted hydrogen, and hydrocyanic, in amounts determined by the partial pressures of the constituent gases, and their respective solubility factors at the temperature of the liquor with which they are in contact. These factors are widely different for the three constituent gases, that for hydrocyanic acid being by far the greatest. Thus, in one work, where the gases leaving the saturator contained 2.9 parts of HCy per 100 volumes of gases at 215° F., the "devil liquor" that separated at 136° F. contained in solution 43 parts of HCy per 100 volumes of CO_2, H_2S, and HCy condensed. Such selective condensation has a very marked effect upon the hydrocyanic acid contents of the gases, and it is only at the saturator exit itself—before the gases have had time to cool—that the full HCy content is found. Exact analysis of the gases at this point presents very great difficulties, and was only successfully accomplished after extended research.

In interpreting any given set of results, consideration must also be given to the treatment of the "devil liquors" condensed. If these are returned to the still, either directly or associated with crude ammoniacal liquor, the dissolved gases will be revolatised in the still and pass forward to the condensing system together with gases derived from the ammoniacal liquor itself. The actual composition of the gaseous mixture leaving the saturator is in such case determined by the CO_2, H_2S, and HCy in liquor contributed from *two distinct* sources of supply. The first, that of ammoniacal liquor, fed into the system from without, from coke oven or gas retort scrubbers; the second, the body of liquor condensed in the system itself, and holding in solution gases which circulate, as it were, between condenser and still. Redistillation of this (devil) liquor profoundly affects the condition of the *hot* gases entering the condensing system, but has little or no effect upon that of the *cold* gases leaving it.

Thus, if—

Volume of HCy per cent. contributed to still gases (CO_2, H_2S, and HCy) by ammoniacal liquor proper be .. X (HCy entering system).

Volume of HCy per cent. contributed to still gases (CO_2, H_2S, and HCy) by devil liquor be .. .. *x* (HCy condensed).

Total HCy per cent. in gases leaving still will be .. .. X + *x*

Then we have—

Volume of HCy per cent. in gases leaving saturator .. .. = X + *x*

Volume of HCy per cent. condensed with devil liquor .. = *x*

HCy leaving in cold gases .. X (=HCy entering system).

Due consideration must be given to the above facts by any investigator who seeks to determine the exact relation existing in any given work between the composition of the liquor distilled and that of the saturator gases obtained therefrom. If the devil liquor is returned to the crude liquor well and fed to the still with the ammoniacal liquor, analysis of a sample of the mixed liquor feed should afford all the data required for determining the relative proportions of CO_2, H_2S, and HCy in the gases leaving the saturator, *hot*. On the other hand, if the devil liquor be pumped *direct* to the still, an analysis of the ammoniacal liquor entering from the heater would afford data insufficient for this purpose; the composition of the gases theoretically obtained therefrom would correspond, in this case, not with that of the gaseous mixture leaving the saturator hot, but with that of the gases leaving the condenser *cold*.

Two examples are given in illustration:—

Example 1.—Devil liquor returned to crude liquor well. Mixed ammoniacal and devil liquors sampled as they enter heater together.

Gases sampled hot by cylinder in exit pipe from saturator 6 feet above the dome. Temperature, 215° F.

	1. Found.	1. Calculated from Liquor.	2. Found.	2. Calculated from Liquor.
CO_2	72.2	71.0	75.1	73.4
H_2S	24.9	25.6	22.5	24.0
HCy ..	2.9	3.1	2.4	2.6
	100.0	100.0	100.0	100.0

Here,

	1	2
HCy found in saturator gases	(X + *x*) = 2.9	2.4
,, calculated from mixed liquors .	(X + *x*) = 3.1	2.6

Example 2.—Devil liquor repumped to still direct. Ammoniacal liquor sampled apart from this.

Gases sampled cold by cylinder and Bunte burette beyond tubular water coolers. Temperature 80° F.

By Bunte burette per 100 vols. dry gases:—

	2.20 p.m.	4.40 p.m.	Mean.
CO_2	74.0	73.7	73.9
HCy			
H_2S	23.6	23.9	23.7
Residual nitrogen	2.4	2.4	2.4
	100.0	100.0	100.0

By cylinder per 100 vols. dry gases :—

	2 20 p.m.	4 40 p.m.	Mean.
CO_2	—	—	—
HCy	2.8	2.9	2.8
H_2S	22.6	22.9	22.8
Residual nitrogen	—	—	—
	100.0	100.0	100.0

Whence, combining these results, and excluding nitrogen by calculation :—

	Found.	Calculated from Gas Liquor.
CO_2	72.9	73.5
H_2S	24.3	23.7
HCy	2.8	2.8
	100.0	100.0

Here,

HCy found in saturator gases .. .. (X) = 2.8.

,, calculated from ammoniacal liquor (X) = 2.8.

Results confirmatory of these conclusions have also been independently obtained at a coke oven works, where excellent agreement was established by the works chemist between CO_2, H_2S, and HCy contents in hot gases leaving saturator and carbon, acid, sulphide, and cyanide in liquor distilled.

Yield of Cyanogen per cent. to Ammonia.—In Report 1905, Table I., p. 46, first column, "Per cent. Cyanogen to Ammonia," comparative figures were given of the average cyanogen contents of liquors calculated as a percentage on the total ammonia present. These figures relate strictly to the condition of the liquors *as distilled* and not as produced in the scrubbing and condensing systems : in some of the individual analyses from which the averages are calculated results relate to mixed devil and ammoniacal liquors, in others to ammoniacal liquors alone—at that date the characteristic part played by devil liquors in raising the cyanide content of the ammoniacal liquors distilled had not been determined. It is not permissible, therefore, to draw any conclusions from the figures there presented respecting the relative *yield* of cyanogen from the four sources of supply under comparison. Even had the devil liquors been excluded from the samples, other factors operate to minimise the comparative value of the figures : the cyanogen retained in scrubbing and condensing systems, however perfect, is only a portion of the whole leaving the retorts, ovens, or furnaces ; and, further, in some of the work under consideration waste gases from the sulphate plant containing CO_2, H_2S, and residual HCy are returned to the crude gas main and rescrubbed before final treatment and discharge.

THE USE OF ZINC IN ASSAYING COPPER MATTE, ETC.

D. M. Levy (*Trans.* I. M. M., May 16, 1907) has substituted zinc for aluminium for removing the copper from solution in the assaying of matte in which iron is also to be determined. Zinc does not interfere with the delicacy of the iodide estimation for copper, so that method may be used. The author finds that with zinc a more complete separation is obtained than with aluminium, the conditions are less rigid,and the method is more suitable than the thiosulphate, and can be advantageously used with most copper-bearing materials met with in works practice, especially when both copper and iron have to be determined. The zinc used is in thin strips about 3 x 0.25 in., rolled up for about half their length, so that they float vertically in the liquid and extend the whole depth of the solution.

The assay is conducted by dissolving the matte in fuming nitric acid, diluting with 20 c.c. of water, 5 c.c. strong sulphuric acid added, and the solution heated to copious white fumes. When cool,60 c.c. of water are added, and the solution heated to a gentle boil, when the zinc is introduced and a small funnel inserted in the mouth of the flask. When the precipitation and reduction are complete, the funnel is washed and removed, and a glass-wool plug placed in it. The solution is then decanted through the wool, the flask rinsed out with dilute sulphuric acid several times, passing the rinsings also through the wool. The iron in the filtrate is then immediately titrated with permanganate or bichromate. The funnel is then replaced in the mouth of the flask, a little nitric acid poured on the wool to dissolve any copper there, washing with about 20 c.c. of water. The funnel is removed, and the iodide method for copper proceeded with in the usual way. A blank should be run on each fresh lot of zinc.—*Engineering and Mining Journal* (New York).

Reports of Companies.

NORTH BORNEO TRADING CO.

At the ordinary general meeting of shareholders last week, Mr. A. J. Scrutton, who presided, said that writing on June 29 last their manager stated that the output of rubber was being slowly increased, and then amounted to 420 lbs. of sheet rubber per month. The better state of the timber market at the end of 1906 and the beginning of this year had eased the financial position in Borneo, and the manager had been instructed to augment his labour force by importing coolies from Java. At present 1,250 lbs. of their rubber was on the way home from Borneo. The Board's policy was to dispose of the Sekong rubber estate, and so provide means to develop other estates. It would be easy to sell the estate at a very low figure, or to a company for the greater part of the purchase consideration in shares ; but, as cash was required to develop other estates, the directors considered it better to nurse the Sekong property a little longer, as they believed that it was possessed of great potentialities. Instructions had been sent to the manager to prepare land on the company's Bode estate for rubber, and it was hoped that planting on that property to a considerable extent would be soon completed. Mr. Cusack asked what acreage they had planted with rubber. Mr. Bennett : Between 300 and 400 acres. A shareholder said that that was a small acreage in view of the land planted by other companies who had only started operations within the last few years. Mr. Bennett said that no one in Borneo besides this company had a rubber tree; other companies had merely seedlings. In answer to further questions, Mr. Bennett said that this company had 13,500 of what he might call "the older trees," 1,400 trees four years and two months old, 10,000 trees from three years and eight months to two years and eight months old, 5,600 trees two years and two months old, 45,000 trees 17 to 28 months old, and more than 100,000 seedlings.

RUSSIAN PETROLEUM AND LIQUID FUEL CO., LTD.

A meeting of the preference shareholders of the Russian Petroleum and Liquid Fuel Company was held on Tuesday last, to consider a resolution empowering the directors "to apply the investments of the reserve fund in accordance with the scheme to be submitted."

The Hon. Evelyn Hubbard, who presided, said what the company was suffering from was inadequacy of production as against the expenses. The directors had been negotiating with another company to get a supply of oil to enable them to meet their engagements. The suggestion was to invest their reserve in the securities of another company, or to advance money to that company, which in return would let them have oil on specially favourable terms. The directors did not want to force this on the preference shareholders, but were willing that the scheme should be postponed to some period in October. Under those circumstances the resolution would not be put to the meeting.

Mr. L. Lever expressed surprise at the decision of the directors not to press the resolution. The fact that they had made a loss was due to their having ceased to market their own oil, and not solely to the unrest in Russia. Seven companies suffering in that way had paid on an average 26%, the highest being 35% and the lowest 18%.

The Chairman said they had outlined the scheme, and the details, which would now have to be altered, would be put before the shareholders as soon as possible.

F. STEINER AND CO., LTD.

The report for the twelve months ended July 31, 1907, states that the working of the business shows a profit, after deducting directors' remuneration and providing £29,978. 6s. for repairs and depreciation of machinery, of £88,091. 18s. To this sum has to be added the balance of £12,289. 18s. 4d. brought forward from last year, making a total available balance of £100,381. 16s. 4d. After making payment of twelve months' interest on the mortgage debenture stock and preference shares, the balance at the credit of profit and loss account is £59,881. 16s. 4d. Out of this balance the directors have placed £22,000. to revenue reserve, and recommend a further six months' dividend at the rate of 6% per annum on the ordinary shares (making 5% for the whole year) leaving a balance to be carried forward of £14,131. 16s. 4d.

Parliamentary Jottings.

HOUSE OF LORDS.

Tuesday, August 27.

The Patents and Designs Bill and the Patents and Designs (Consolidation Bill) were read the third time.

The Employers' Liability (Insurance Companies) Bill was read the third time.

Wednesday, August 28.

ROYAL ASSENT TO BILLS.

Royal Assent was given by Commission to 62 Bills, including the following :—Limited Partnerships, Advertisements Regulation, Patents and Designs, Patents and Designs (Consolidation), Factory and Workshop, Public Health (Regulations as to Food), Companies, and Whale Fisheries (Scotland).

HOUSE OF COMMONS.

Tuesday, August 27.

THE PREVENTION OF CORRUPTION ACT.

In reply to Mr. Lupton, the Attorney-General stated that there have been four applications for his *fiat* for prosecutions under the Prevention of Corruption Act, 1906. *Fiats* have been granted in three cases ; one is at present under consideraton. Convictions were obtained in all cases.

CONSULAR REPORTS.

The Foreign Secretary, replying to Mr. C. Price, said he would consider whether any general instructions could be given with advantage to Consuls abroad, to furnish with reports on the trade of foreign countries particulars as to the conditions of labour, wages, and cost of living. He thought, however, such matters were better suited for special inquiry by experts than for the regular reports of Consuls.

NICKEL FOR COINS.

In reply to Mr. Essex, Mr. Runciman stated that the Chancellor of the Exchequer did not believe that the substitution of nickel-bronze for bronze would be satisfactory to those who use most largely the existing subsidiary bronze coinage. Aluminium would not be a satisfactory metal for our coins, and both nickel-bronze and aluminium would be more costly. A concurrent issue and circulation of nickel and bronze coins would be attended with great practical difficulties, and the substitution of nickel for bronze in a coinage in which silver pieces of small denomination are so largely used would probably lead to much confusion and inconvenience.

Broken Hill Proprietary Co.—The following cable has been received from the head office in Melbourne :—Half-yearly statements have been issued showing a profit for the six months ended May 31 of £308,238. Net assets, £686,420., and profit and loss account shows a credit balance of £722,285. ; £17,386. has been expended in construction during the half-year, of which amount £10,349. has been on account of practically duplicating various plants ; 18,199 tons of ore treated in the furnaces at Port Pirie more than during past half-year, which is due chiefly to the additional amount of sintered slimes treated—43,352 tons, against 28,539 tons. Explorations in the lower levels are being vigorously prosecuted. Developments in the lower levels are estimated to have added to ore reserves 245,000 tons, and, as the tonnage of ore raised has been 290,000 tons, the estimates of ore remaining in the mine are much the same as past half-year. The total expenditure on account of exploration work amounts to £25,621., equal to 1s. 9d. per ton of ore raised. Concentration plant doing good work with better recovery in all metals, but working costs have increased all round, due to increased wages and the higher rate paid for water. Alterations have been made in the zinc concentration plant, and satisfactory results have been attained in the direction of better recovery metals ; average grade of concentrates, 41.81% zinc, against 40.66% in the past half-year, while for the past few weeks it has been over 43%. Output for the past half-year has been 2,695,800oz. silver and 29,427 tons pig lead. Average net prices obtained during the half-year :—Lead, £18. 6s. 5d. per ton ; silver, 2s. 9$\frac{7}{8}$d. per oz. fine. Profit for the half-year is equal to £1. 0s. 9d. per ton of ore treated, as compared with £1. 1s. 1d. per ton for last half-year. The increase in wages is equal to 2s. 2d. per ton of ore.

THE BOARD OF TRADE RETURNS.

(To the Editor of the Chemical Trade Journal.)

Sir,—The banging of drums and the clashing of cymbals over the returns for July's foreign trade awaken a suspicion as to the equal accuracy of some of the totals when compared with what the reader imagines them to represent. The totals appear unequal for purposes of comparison, as the following contentions will exemplify.

The home exports are valued "f.o.b.," whilst the imports are valued "c.f.i.," and the re-shipments "f.o.b."

What do these symbols mean ? "f.o.b." means free on board, and "c.f.i." means cost, freight and insurance.

Home exports are valued at £40,452,000., imports at £52,213,004., and reshipments £7,388,000.

Take an article valued at £100. Firstly, this is to be exported, *i.e.*, sold, at a free on board price which includes all incidental expenses until the goods get on board the export steamer. They may be :—Cost of article, £100. ; railway carriage, dock dues, etc., 15s. ; total, £100. 15s.

Therefore the "f.o.b." value is £100. 15s., although only £100. worth of goods have been exported.

Secondly, the article is to be imported from abroad, *i.e.*, bought at "c.f.i." price, which includes all expenses from the foreign factory until the goods arrive at the English port. They may be :—Cost of article £100. ; sea freight from foreign port to England, £6. ; dock dues, railway carriage, &c., 15s. ; marine insurance, 7s. 6d. ; postage and petties, 5s. ; agent's commission on the transaction (5% on £107. 7s. 6d.), £5. 7s. 4d.—total £112. 14s. 10d.

Therefore the "c.f.i." value of the merchandise is £112. 14s. 10d., although only £100. worth of goods were bought.

Thirdly, as regards reshipments, when the £112. 14s. 10d. came to be reshipped, at what value would this amount be entered ?

Assuming these practical illustrations to be the method adopted in compiling the Board of Trade returns, it will be seen the "shipping charges" are computed as "goods." When the totals run into millions sterling, the difference between "f.o.b." and "c.f.i." valuations become startling.

From a Customs point of view, if duty is levied, the "c.f.i." valuation is excellent, as customs duty would be paid on £112. 14s. 10d., and not on £100., the value of the goods.

Can anyone offer any other solution ?

Yours, etc.,

London. Ajax.

CASEIN.

(To the Editor of the Chemical Trade Journal.)

Sir,—Kindly permit me to ask, through the medium of your columns, if anyone can tell me where casein is manufactured. I have frequently been shown cigar-holders, mouthpieces for feeding bottles, and other solid articles made from this by-product of milk, but I should very much like to know where and in what quantities this easily obtained raw material is being scientifically utilised, and what are the prospects of the industry.

Yours, etc.,

24th August, 1907. Liverpool Inquirer.

Electrical Measuring Instruments.—Messrs. Archibald Constable and Co. announce that they will publish during the autumn a new and comprehensive work on electrical measuring instruments, recorders, meters, etc., by Kenelm Edgcumbe, M.I.E.E.

Transvaal Industries.—The Government has decided to appoint a Commission to inquire into the condition of existing Transvaal industries, the possibility of their extension, and what encouragement and protection for them are necessary. The Commission is further to inquire into the effect of the Customs Union, the extent of white labour as compared with coloured labour, the extent to which the use of Asiatic labour in the neighbouring Colonies is prejudicial to Transvaal industries, the effect of the parcels post on local trade, and the desirability of amending the Customs tariff.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in the Construction of Twin or Coupled Gas Producers. Mason's Gas Power Co., Alma Works, Levenshulme, Manchester, and T. Wright, 39, Cringle Road, Levenshulme, Manchester. British Patent, 16,218. July 18, 1906.

This invention refers to what are known as twin or coupled gas producers, that is, gas producers built integral with each other, with a dividing wall common to both, and of rectangular or circular construction in plan, or with the outer ends round and the sides (front and back) flat. The invention also refers to that construction of twin or coupled producers in which the steam and air for working the same are admitted and the space below the grate cleaned from the opposite ends of the combined structure.

With such an arrangement it has been impossible for two pairs of such producers to be placed closer together than the necessary space for pokering would allow, and with the pokering done at each end of the structure it has not been practicable for more than two producers to be built integral with each other. Another objection has been that, with the producers flat or straight-sided in plan, they have, under the expansion of the brickwork, tended to bulge outwards, back and front, and so much so that a considerable number of tie rods have been necessary in order to resist the bulging, as well as a very strong outer casing, thus adding greatly to the cost of making the producers.

The present invention has for its object first, to couple the producers in a way which permits of two or more pairs of such producers integrally built being placed and used in less compass than the old construction; secondly, to couple the producers in a way which permits of any number being coupled to each other in a row in a minimum of floor space, whilst allowing the air and steam to be admitted at the ends of the grate and the space below the grate cleaned from each end, and also whilst allowing the water-sealed ash pit to lie at right angles to the longitudinal axis of the grate, and thirdly, so to construct the producers and their casings that they, of themselves, will resist any tendency to bulge outwards, and thus allow of the use of fewer tie rods, and the use of an outer casing of much less strength than previously necessary, with the consequent advantages of reducing both the initial cost of manufacture and the cost of upkeep. Two sheets of drawings show the construction.

Improvements in or Relating to the Extraction of Tin from Ore. R. W. E. Macivor, Glengall Road, Millwall, London, E., and M. Fradd, Finsbury House, Blomfield Street, London, E.C. British Patent, 17,002. July 27, 1906.

In the inventor's previous application No. 10,943, 1905, was described a process for extracting tin from its ores by the reducing action of producer gas or water gas, and the present invention is an improvement upon that process.

Hitherto it has been proposed to reduce tin ores by means of a jet consisting of air and either oil or gas. According to this invention reduction is carried out by means of the partial combustion of water or producer gas.

In the previous application the furnace, conveniently a cylinder, in which the reduction takes place, was heated externally to the necessary temperature. According to this invention, instead of externally heating the cylinder, the charge in the cylinder is heated internally by partial combustion of the reducing gas.

In carrying out this invention the finely divided ore is introduced as before into a furnace provided with any suitable means for agitating the contents during the process of reduction. The reducing gas, such as water-gas, is derived from any convenient form of producer, and is passed into a combustion chamber in proximity to the cylinder or forming a part of it, and the combustion chamber is constructed and arranged in any manner which will permit of the introduction of the combustible gas and of air, and of the careful regulation of their proportions. The amount of air introduced is sufficient only for partial combustion of the reducing gas, and the hot mixed gases are then utilised in the cylinder or reducing chamber, both to heat the ore to the desired temperature and to effect the reduction of the tin to metallic form. The temperature thus produced may conveniently be 600° C. or more, but sufficient hydrogen or other reducing agent is still left in the unconsumed gas for the purpose of carrying out the reducing process.

Improved Manufacture of Cement for Building and like Purposes. P. Timoffeeff, 23, Morskaya, St. Petersburg, Russia. British Patent, 17,006. July 27, 1906.

This invention relates to the manufacture of a fire-proof building cement consisting of sulphate of lime, siliceous mortar, and dextrin or casein, the two last constituents each amounting to 2—10% of the mass, the rest of which is sulphate of lime. Carbonate of lime may be mixed in certain proportions with the sulphate of lime, and the mixture calcined at a temperature about or below 150° C. and ground to fine powder before being mixed with the other constituents. When sulphate of lime, either from natural sources or artificially made, is used without carbonate of lime, it is calcined in a furnace or heated in a boiler until it is dehydrated (at about 130° C.), and finely ground. To impart hydraulic quality to the cement, in either case, tufa, consisting of silicates of alumina, substances obtained by heating siliceous alumina, puzzolanas, trasses or the like, materials obtained by calcining clays, or blast furnace furnace slags, may be added. When the cement is to be fire-proof in high degree about a suitable proportion, such as 2—10%, of calcium fluoride may be added. To retard shrinkage some kind of flour may be added to the cement, and when a coloured cement is required some suitable colouring matter may be mixed with the other materials. The proportions in which the ingredients are to be mixed in order to make the cement vary with the object for

Digitized by Google

which the latter is intended. For a very strong cement, for instance, 24 parts of anhydrous calcium sulphate and six parts of calcined clay may be mixed with 1 part of dextrine and 1 part of siliceous mortar.

Improvements in Effecting the Removal of Impurities from Hydrochloric Acid Gases. G. W. Johnson, 47, Lincoln's Inn Fields, London (communicated by Verein Chemischer Fabriken, Mannheim, Germany). British Patent, 16,910A. July 26, 1906.

Besides compounds of chlorine and arsenic, hydrochloric acid gases contain other compounds such as sulphuric acid, chlorine, nitrosyl compounds, and iron chloride, which are impurities. This invention consists in employing the treatment with oils as described in Specification No. 16,910 of 1906, as a means also for effecting the removal of the impurities from such gases, as it has been found that thereby not only arsenic, but also the greater part of the other impurities can be removed, so that gases are in this way obtained which are eminently suitable for the manufacture of industrially pure liquid hydrochloric acid, and also for the manufacture of chlorine by the Deacon process. The claim is:—The removal from hydrochloric acid gases of impurities other than arsenic by subjecting the said gases to treatment with oils as described in the Specification of the Application for Letters Patent No. 16,910 of A.D. 1906 as applied to the removal of arsenic.

Improved Process for the Extraction of Sulphur. M. Rohleder (Chemische Fabrik Phœnix, Rohleder and Co.), 2/3, Wallgasse, Danzig, Germany. British Patent, 23,967/1906. Date claimed under International Convention, November 15, 1905.

The process consists in bringing the solution containing the sulphur into contact in a finely divided condition with a warm liquid in which both the sulphur and its solvent (generally bisulphide of carbon) are insoluble. The bisulphide of carbon is speedily eliminated from the small portions. The sulphur separated out no longer retains bisulphide of carbon or the like, as in other processes. The process is therefore free from danger, and in particular prevents the ignitions which so easily occurred with the processes hitherto employed on emptying the vessels. Owing to the fact that the bisulphide of carbon was formerly directly driven out of the solutions, the sulphur left behind formed a large solid mass, which adhered firmly to the walls of the distillation vessel, from which it had to be forcibly removed. The division of the solution of the sulphur in bisulphide of carbon and the quantity of hot liquid which this liquid reaches, must be selected in such a manner that the bisulphide of carbon is speedily eliminated from the small separate portions so that no collection of considerable quantities of the solution takes place, and that the temperature may be kept such that the bisulphide of carbon quickly distils over.

Improvements in Rotary Kilns. W. C Shiner, Catasauqua, Lehigh Co., Pa., U.S.A. British Patent, 443. January 7, 1907.

The inventor claims:—In apparatus of the type set forth, the arrangement of a conveyor extending from the lower end of a supply chamber through the lower end of a separate settling chamber so that the whole quantity of dust deposited may be conveyed back to the rotary kiln.

A Super-alkalinated Dry Soap in Compressed Cakes, and the Method of Manufacturing the same. The Société Française "La Cremouline," 99, Rue de Picpus, Paris. British Patent, 2,519. January 7, 1907 (date claimed under International Convention).

This invention relates to a soap specially intended for washing linen and for degreasing, and to the process of manufacturing the same. The soap is a dry product which, though containing caustic salts, is made up in the form of compressed cakes.

The invention consists essentially in agglomerating a mixture of soap powder and caustic alkaline salts with the addition of a little glycerine or other polyatomic alcohol and some mineral spirit, by submitting the whole to compression.

Improvements in Ore Washers or Concentrators. E. A. Wall, 32/D F., Walker Block, Salt Lake City, Utah, U S.A. British Patent, 7,801. April 3, 1907.

This invention relates to an ore washer or concentrator, characterised by a reciprocating sluice or body, having a raised head end to give the proper head to the water and ore, an outlet for the waste material and water at the tail end above the bottom; a riffled outlet in the bottom of the sluice or body; a receptacle for the concentrate having means for discharging the concentrate and a pressure water supply; and means for imparting a sudden bump at the head end towards the tail to cause the concentrate to be fed towards the tail end.

Improvements in or Relating to the Extraction of Sulphur from Gangue or other Metal. A. J. Boult, 111/112, Hatton Garden, London (communicated by Dr. E. Gunther, 6, Markt, Eisleben, Germany, and R. Franke, 44, Zeissingstrasse, Eisleben, Germany) British Patent, 11,187. May 15, 1907.

The inventor observes that the extraction of sulphur from a mixture with gangue or other admixtures of any kind has hitherto offered many difficulties, owing to the fact that it was not always possible to separate the sulphur from the admixtures completely and in a convenient manner. The use of well-known sulphur extracting means is combined with more or less great drawbacks. Carbon sulphide is very volatile and explosive, tetrachloride of carbon is also volatile, and both substances have only a limited power of solution of sulphur, particularly tetrachloride of carbon, which, in the techincal meaning of the word, cannot be considered really as a solvent for sulphur. Petroleum with very high-boiling point has also been recommended for the extraction of sulphur, but has not been found suitable, as, in spite of all precautions, it was impossible to avoid ignition of the vapours, and further, there took place a gradual formation of resin, and its removal from the extracted sulphur offered difficulties.

It has been found that tetrachloride of acetylene, which can be easily and cheaply prepared by the process described in the German Patent No. 154,657, has, at a high temperature, a power of dissolving sulphur which is much greater than that of the substances before specified. While tetrachloride of acetylene at an ordinary temperature dissolves only about 1% of sulphur, in the neighbourhood of its boiling-point, 146° C., it can be mixed with molten sulphur in any proportion in the same manner as, for instance, alcohol and ether are mixed at an ordinary temperature. The extraction can be effected, for instance, in a Soxhlet apparatus or similar extraction apparatus. Or the sulphur-containing substance can be heated with tetrachloride of acetylene; the hot solution of sulphur is separated from the undissolved part, cooled; the sulphur precipitated is separated from the solution; and the solution, containing a small quantity of sulphur, is utilised for a new extraction. The last traces of tetrachloride of acetylene can be easily expelled by steam from the sulphur extracted.

Instead of using tetrachloride of acetylene alone, mixtures of tetrachloride of acetylene with other liquids, more particularly with those which in themselves also dissolve sulphur, more particularly hydrocarbons, can be used. This makes the process of extraction cheaper, without reducing the power of solution of the mixture below the technically applicable limit. For instance, a mixture of 100 grammes of tetrachloride of acetylene and 100 grammes of xylol dissolve at the boiling point 80 to 90 grammes of sulphur.

The property of tetrachloride of acetylene to dissolve sulphur can be used with special advantage for enriching gas purifying substances in their contents of cyanogen, which enriching is required for the chemical extraction of cyanogen compounds. This is effected in such manner that the gas purifying mass is regenerated every time it becomes inoperative, by exposing it to the oxidising action of the air, and by utilising it again after regeneration. This regeneration and further utilisation are continued until cyanide compounds have accumulated in such quantities that the treatment of the mass for obtaining cyanide compounds appear sufficient to repay extraction. This utilisation of tetrachloride of acetylene is based on the fact that a compound of sulphur and iron is formed in the gas purifying mass—which, as regards its chemical composition, chiefly comprises oxide of iron (Fe_2O_3) or hydroxide of iron ($Fe_2(OH)_6$)—by the action of the sulphuretted hydrogen of the gas to be purified, the said combination of sulphur and iron separating in the open air sulphur, and forming again oxide of iron or hydroxide of iron; the sulphur separated can be removed by means of tetrachloride of acetylene without the mass becoming unsuitable for further use as a gas-purifying mass.

Artificial Camphor Production in France.—It is reported that a company has recently been formed under the title of the Société Le Camphre, of 68, Boulevard de Strassbourg, Paris, for the purpose of manufacturing camphor by means of a special process. The company has received various patents, including those of MM. Dubose and Behal. Works have been acquired at Bonnieres. It is expected that production will be commenced in the course of a few months.

SULPHUR.—The negotiations between the Italian (Sicily) and American producers having fallen through, the former are now threatened with direct competition by the Union Company of Louisiana, whose first consignments to Europe are expected next month. It looks like war to the knife.

SUGAR CONVENTION.—The additional Act of the Sugar Convention was signed on Wednesday last at Brussels. In virtue of this arrangement the International Union has been extended for a fresh period of five years to date from September 1, 1908. From that date Great Britain will be relieved of the, obligation of penalising bounty-fed sugars, but the other contracting States will have the right to demand that sugar brought to Great Britain and exported to their territories shall be acccompanied by a certificate stating that no portion of it has come from a country which gives bounties for the production or exportation of sugar.

Trade Notes.

ADVANCE IN THE PRICE OF COAL.—The price of coal was considered at a meeting of Lancashire colliery proprietors, held at Manchester on Tuesday last, and it was decided that on and after September 1st the price of house coal should be raised by 1s. 8d. per ton, and the price of engine coal by 10d. per ton.

SALT IMPORTS INTO HOLLAND.—The Board of Trade are in receipt, through the Foreign Office, of a translation of a Dutch Royal Decree, dated 17th July, 1907, which provides for the exemption from excise duty of salt required in the preparation of freezing mixtures in factories and workshops.

UNITED INDIGO AND CHEMICAL CO.—The balance sheet of the above-named company showed a profit of £5,022., and the directors, at the annual meeting on Thursday, at Manchester, recommended that, after the payment of a dividend on the preference shares in respect of the six months ended June 30 last, a balance of £1,602. should be carried forward. The Chairman, Mr. C. J. Whittaker, said the profits last year amounted to £7,300. This year they totalled £5,000. This decrease was partly due to the writing-off of Consols, and the opening of a branch. The company's prospects were better than last year.—Mr. Isherwood, Huddersfield, said he was surprised to find the profits had decreased in a year which had been a most prosperous one. Dissatisfaction was also expressed by other shareholders, and the Chairman said that although the profits were low, the management had done a great deal of work. Continuing, Mr. Whittaker said he would much prefer not to be chairman of the company, but he wanted to stand by it. For every thousand of pounds of indigo and indigo products sold per week previously, they only sold one hundred now, but that did not mean that they had lost a large proportion of their trade. They still had a larger proportion of the trade than they had previously. They were working a dyeing trade now, and business was very satisfactory. It was unfortunate that the indigo trade went so quickly.—The report was adopted, and the question of the election of more directors was left for a subsequent meeting.

NEW AGRICULTURAL METHODS IN ITALY.—In reporting upon the trade of the Province of Lille, Mr. Consul Cocoto states that marked success has attended the efforts of the local Consorzio to persuade local landowners, and also country labourers employed by them, to entertain and adopt modern ideas as to the cultivation and protection of the vine. The Government is also endeavouring to persuade landowners and farmers to abandon the old systems of husbandry, and to this end travelling professorships of agriculture have been instituted in this and other agricultural districts. That in Brindisi is under the direction of Professor D'Ambrosio, who has already succeeded in effecting the introduction of rational improvements. The professor publishes a fortnightly pamphlet, in which he draws attention to the agricultural incidents of the moment, practically advising thereon. He visits estates and farms in order that he may impart on the spot such technical and theoretical ideas as to modern systems of agriculture and the results to be obtained therefrom as may be opportune. He lectures alike to the proprietor and to the worker in villages and country centres with good results, and, in view of the fact that the greater part of the soldiery is drawn from the agricultural population, he visits the barracks to talk to the men, in the hope that on their return to their homes they will preserve some of the ideas he has attempted to disseminate amongst them. He further explains the advantages to be obtained by the use of mechanical instruments of agriculture in the place of the simple plough and harrow (of almost primeval form), which have hitherto been in use. His advice under this head has been favourably listened to, and each year agricultural implements of all descriptions are being increasingly used. He is at all times prepared to advise on agricultural subjects; and also to analyse chemically soils with a view to proposing the proper manure or other treatment required. He arranges and cultivates model fields for particular branches of agriculture, to demonstrate the benefits to be obtained thereby. He is now doing his utmost to introduce the principle of co-operation in the interest of oil and wine producers, fruit growing, cheese making, bee keeping, silkworm egg rearing, and all the numerous subsidiary branches of agriculture. The advice and assistance of the professor being entirely gratuitous, increasingly favourable results are anticipated, as owners and labourers understand and realise the value of the counsel given them, and conclude that it is to their personal advantage to follow it.

Cape Profit Tax.—The Cape House of Assembly has passed a measure imposing a profit tax of 10% on diamond and copper mining companies earning over £50,000 per annum.

Anglo-American Oilfields Co.—Mr. J. S. Bergheim, presiding at the statutory meeting of this company, on Thursday last, said that all the machinery had been ordered since they were constituted two months ago, and had arrived at the ports. When they would start drilling he could not say definitely, but it was hoped to commence by December 1. Nothing had transpired since they took over the property to weaken their faith in it as an oil venture.

The Census of Production.—The first meeting of the Special Advisory Committee for the Coal Mining Industry was held on the 15th inst., at the Board of Trade. There were present Mr. A. Wilson Fox, C.B. (in the chair), Mr. F. J. Jones, Mr. R. Baird, Mr. W. S. Barrett, Mr. G. J. Binns, Mr. Gascoigne Dalziel, Mr. R. Guthrie, and Mr. T. Ratcliffe Ellis representing the Mining Association of Great Britain; Mr. Malcolm Delevigne and Mr. W. A. Atkinson representing the Home Office; Prof. S. J. Chapman, Mr. G. J. Stanley, C.M.G., and Mr. H. W. Macrosty.

The Revenue.—Up to the end of last week the receipts into the national exchequer were £50,033,017 for this financial year, or £1,500,000 more than in the corresponding period of last year. The increase in the revenue is mainly in estate duties, excise, and the income tax, but there are smaller gains from the postal and telegraphic services. Indeed, all the chief items of revenue show increases, except the customs. The payments out of the exchequer are, so far, this year, £600,000 below those for the corresponding period.

Fire at a Dye-Works.—On Tuesday last a serious fire occurred at the dyeing works of the Calico Printers' Association, situated at Barrow, between Clitheroe and Whalley. The finishing rooms were saved, the rooms containing a large quantity of stored block work. With the loss of machinery the damage is estimated at not less than £12,000 to £15,000, which is mainly covered by insurance.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, August 13th, 1907.

(Rate of Exchange, $4.86¾ = £1.)

Nitrate of soda is in pretty good demand with prices remaining unchanged at $2.50. per 100 lbs. Sulphate of ammonia has not improved in the local market, but prices are well maintained at $3.05. to $3.07½. per 100 lbs. Grey muriate for galvanising is selling at 5¾c. to 6¼c. per lb., as to make. White electrical is in free supply and selling rather freely at 5¾c. per lb. Lump sal ammoniac is steady at 9¼c. per lb. Lump carbonate of ammonia is moving slowly at 7⅝c. to 7⅞c. per lb. Bleaching powders are not in very great demand, and are quoted at $1.30. per 100 lbs. Alkali and caustic soda remains as previously quoted. Sulphate of copper is weak; the Syndicate price is 7c., but this can be shaded in large quantities. White powdered arsenic is dull, but prices are well maintained; prompt deliveries are selling at 7c. per lb., while futures have been offered at 6¾c. to 7c. per lb. Red Saxony arsenic remains unchanged at price last quoted. Calcined potash, 80-85%, is reported at 3¼c. to 3⅜c. per lb., and hydrated 4¾c. per lb. Caustic potash (75%) has improved, but is quoted at same price. Chlorate of potash and soda are well maintained at prices last quoted. Bichromate of potash is still selling at 8¾c., and soda at 7⅛c. per lb. Prussiate of soda remains unchanged at 9½c. per lb. Prussiate of potash continues dull, and is quoted at 16c. per lb. Oxalic acid is selling steadily at 8¼c. per lb., while futures are quoted at 8c. per lb.

THE LONDON METAL MARKETS.

Thursday.

Copper: Standard brands, £79. 5s. to £79. 10s. cash, and £77. 15s. to £78. three months. Tin: G.M. quality, £169. 10s. to £170. cash, and £169. 7s. 6d. to £169 17s. 6d. three months; English, £173. Lead: soft foreign, prompt, £19. 10s.; August shipment, £19. 5s.; November, £18. 15s.; English, £19. 15s. Spelter: Ordinary brands, £21. 17s. 6d.; ex ship hard, £18. 10s., f.o.b. Antimony, £36. to £38.; ore, £8. 10s. to £9. 10s. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6 16s. Nickel, £175. to £185. Aluminium, £158. to £162. Wolfram, 45s. to 50s. Pig-iron closing prices: Cleveland 56s. 11d. cash, and 56s. 11½d. one month.

FERTILISER MATERIALS.

Friday.

Quietness still prevails in all departments for manure material, but prices are fairly well maintained.

No fresh development has taken place in mineral phosphates. Raisers of all grades, being well sold ahead, still maintain a firm attitude.

£4. 17s. 6d. per ton, nett, c.i.f. terms Liverpool, would be accepted for East Indian bone meal for shipment, but there is little demand for this material at present. On spot, £5. 5s. to £5. 10s. per ton, according to quality, ex store, is asked.

Nitrate of soda still keeps a quiet market, but quotations remain steady at 11s. 1½d. per cwt. for ordinary, and 11s. 4½d. per cwt. for refined quality, on spot.

TAR AND AMMONIA PRODUCTS.

Friday.

Benzols: Values are given at 8¾d. to 9d. for 90's, and 9d. for 50-90's. Crude tar, 15s. 6d. to 20s. per ton, Thames; 1¼d. to 1⅜d. per gallon, delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, 26s. to 26s. 6d., f.o.b.; Gas Company, 29s.; East Coast, 25s. to 25s. 6d.; West Coast, 24s. to 24s. 6d., forward 2s. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 10½d. to 11d.; pure, 1s. 6d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5¾d.; 60%, 1s. 8d.; 75%, 1s. 11¾d. to 2s.;

Digitized by Google

crystals, 39-40, 5¾d.; 34-35, 5¼d. Cresylic, 95%, 1s. 0½d. to 1s. 1d. Anthracene, 40 to 45% A, 1½d. to 1⅝d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia firm. Nearest values are:— Beckton, £12.; Beckton terms, £11. 11s. 3d. to £11. 12s. 0d.; London, £11. 15s. to £11. 10s. 3d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.

Nitrate of soda, ordinary, 11s. 3d., and refined 11s. 9d.; Liverpool, ordinary, 11s., refined 11s. 1½d. Official quotations:—Cargoes off coast or due, 11s. 1½d.; ditto for prompt shipment, 11s. 6d.

MISCELLANEOUS CHEMICAL MARKET.

THURSDAY.

Business generally in the principal products of the alkali trade is somewhat quiet, and values are unaltered. Bleaching powder is still offered on basis of £4. rails for 1908 contracts, and for prompt £4. 7s. 6d. softwoods f.o.r. Ammonia alkali, soda crystals, and bicarbonate are without change. Caustic soda, 70%, £9. 15s.; 74% £10. 5s. f.o.b. There is some small inquiry for the latter over next year, but prices have not yet been settled. Chlorates are quiet at 3½d. per lb. Sulphate of copper continues weak at £26. 10s. to £27. f.o.b. for prompt and early shipment. Spring delivery is quoted £26. f.o.b. Saltcake steady at 40s. f.o.r. Recovered rock sulphur, bags, £4. 10s. to £4. 11s. 3d. f.o.r. Caustic and carbonate of potash are still in short supply, and prices are firmly maintained. Prussiates a shade weaker for near delivery. Potash at 5⅝d. and soda 3½d. per lb. Bichromates quiet at 3½d. and 3d. for potash and soda respectively. Lead salts are in better request, and quotations rule steady. Foreign white, £32. 10s. c.i.f.; brown, £26. 5s.; nitrate, £34. to £34. 10s. per ton. There is a fairly good demand for white powdered arsenic, both for home and export, and prices are firm at £31. to £31. 10s. Garston-American brown acetate of lime easy at £8. 7s. 6d. c.i.f.; grey, £12. 10s. per ton. Acetate of soda, £17. to £17. 5s. c.i.f. Oxalic acid is now offering for 1908 delivery at 3¼d., and some business has been done round and about this figure.

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes in limited supply at 35s. 6d. to 36s. per cwt. Pearl ash nominal. Cutch steady. Gum arabic quiet. Gum copal: a small lot of Sierra Leone sold at auction at 9d. per lb. Logwood and fustic quiet. Castor oil steady at 3 11/16d. for first pressure French; 3½d. for second pressure French; 3⅜d. to 3 7/16d. for good seconds Calcutta; and 3 11/16d. for August-September, September-October shipment of the latter. Gambier: Block, 18s. 7½d. to 19s.; 18s. for June-July; 18s. 1½d. for July-August; and 18s. for August-September shipments. Cubes, 28s. 6d. to 29s.; and 27s. 9d. for August-September and September-October shipments. Shellac steady at 192s. 6d. to 195s. for T.N. orange on spot. American powdered starch, 10s. 3d. on spot, and 9s. 9d. c.i.f., for shipment; pearl, 9s 9d. on spot, and 9s. 3d. c.i.f., for shipment. Glucose: American liquid, 43°, 11s. on spot, and 8s. 9d. c.i.f. for shipment. Cream of tartar: 98%, foreign powder, 81s.; 95%, 79s. Tartaric acid: English, 11¼d. to 11⅜d. on spot; foreign, 11d. Citric acid: English, 1s. 10½d.; foreign, 1s. 10¼d.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

OILS.—Palm oil steady, sales including Benin, £27. 6s. to £27. 10s. on spot, and £27. 15s. for October-November shipment; Lagos, £29. 5s. on spot. Cottonseed oil steadily held at 30s. 9d. to 31s. 3d. for Liverpool refined in export barrels. Linseed oil firm at 24s. 3d. to 25s. for Liverpool makes in export casks. Tallow firm at 32s. to 34s. for Norths; 34s. 7½d. to 34s. 6d. c.i.f. for South American mutton; and 34s. 3d. c.i.f., for South American beef. Rosin steadily held. Turpentine quiet, at 41s. 9d. per cwt. on spot. Petroleum steady at 6½d. for Russian and Roumanian and 7d. to 8d. for American refined oils. Petroleum spirit in fair demand, at 1s. 0½d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

HULL PAINT, OIL, AND COLOUR REPORT.

WEDNESDAY.

OILS.—Seed oils have been improving in value all the week. In the case of cotton oil this may be attributable to the small imports of seed, but linseed oil may have been influenced by the improved demand for seed, which is selling in London at increased prices. Imports during the year at all ports have been heavy, and crops generally are good; therefore it is difficult to understand, unless it is spasmodic and firmly held. Among the principal imports here to date, as against the same a year ago, are:—Wheat, 2,714,855 qrs., against 2,503,865 qrs.; flour, 142,262 cwts., against 247,163 cwts.; linseed, 513,492 qrs., against 346,354 qrs.; rapeseed, 61,509 qrs., against 51,828 qrs.; cottonseed, Egyptian, 126,413 tons, against 109,939 tons; other kinds, 125,172 tons, against 100,037 tons; oilcake, 17,866 tons, against 28,287 tons; hemp, 89,479 cwts., against 114,303 cwts.; olive oil, 3,484 tuns, against 2,934 tuns. Amongst the weekly imports are:—Margarine, 2,902 cwts.; lard, 4,158 cwts.; sugar, 23,515 cwts.; glucose, 2,261 cwts.; hides, 3,206 cwts.; oilcake, 360 tons; colours, 2,677 packages; wool, 14,436 lb. Exports:—Oil, 9,714 cwts.; colours, 1,936 packages; chemicals, 2,169 packages; linseed oil, strong, from 10s. to 15s. per ton higher, spot naked, 22s.; September-December, 21s. 9d.; January-April, 20s. 9d.; boiled and refined, £1 to £1. 10s. per ton extra. Exports for the week:—1 ton China, 3 Denmark, 7 Germany, 30 India, 7 Norway, total 48 tons. Linseed: La Plata spot, 41s. 6d.; August-September, 42s. 3d.; September-October, 500 tons sold at 42s. 3d., and 1,000 tons sold at 42s. 6d.; December-January, 41s. 6d.; January-February, 41s. Refined cotton oil, strong, at 7s. 6d. to 10s.; advance spot, 28s.; August, 28s.; September-October, 27s. paid; November-April, 24s. paid; casks £1, and barrels £1 7s. 6d. per ton extra. Exports for the week:—6 tons France, 28 Germany, 45 Holland, 1 Norway, total 80 tons. Cottonseed dearer; spot, £8. 7s. 6d. paid; to arrive £8. 6s. 3d. paid; August, £8. 5s.; September-November, sold at £8., closing £8. 2s. 6d. buyers; Bombay, September-October, sold £5 15s. Turpentine, quiet, 41s. 6d.; September-December, 42s. 9d.; January-April, 44s. Rosins unchanged. Castor oil, November-December, £30. 15s. Russian business done at 20s. 6d.

OILCAKES.—Generally a firm market, and fair demand; 95% pure linseed, £7. 5s. to £7. 7s. 6d.; Canadian, £7. 10s.; oilcakes, £6. 5s.; cotton cakes, best, £5.; Bombay, £4.; both firm,

TYNE CHEMICAL REPORT.

THURSDAY.

Chemicals continue in steady demand. Soda crystals in good request locally at £2. 17s. 6d. to £3. 2s. 6d. per ton, gross weights. Bleaching powder steady at £5. to £5. 5s. per ton. Caustic soda, 70%, £9. 15s.; and 76-77%, £10. 10s. per ton. Sulphur firm at £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2 cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett; do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5/7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (saltcake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 56-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—The general tone of the coal market remains firm, and for good gas and steam coals was, if anything, stronger.

For current shipment quotations are as under:—Best Northumbrian steam, 16s. to 16s. 6d. per ton; second qualities, 15s. to 15s. 6d. per ton; small steam, 10s. 6d. to 11s. per ton; best gas coals, 15s. 6d. per ton; second qualities, 14s. 6d. per ton; Durham bunker coals, 14s. 3d. to 15s. per ton; coking coals, 14s. 6d. per ton; household coals, 16s. to 17s. 6d. per ton; gas coke, 20s. per ton; foundry coke, 25s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, Thursday.

There is little or no change in the ordinary heavy chemicals. A fair current of spot business is passing at the recent figures, with an increasing inquiry respecting forward supplies. Sulphate of copper has had a further fall. Sulphate of ammonia, prompt f.o.b., Leith, holds at about the mark of a week ago, with moderate business reported. Forward dealing is again nominal for the time, the last being £12. 2s. 6d. Leith, f.o.b. Creosote oil is still a firm market. In the mineral oil and paraffin section the activity of movement is retained; season's burning oil contracting is still going on, and the makers will soon be about fully booked up to estimated forward production. In the mineral lubricants 865° gravity has become scarce, and its tendency is upwards. The soid paraffin and paraffin spirit are all very steady and firm of price.

Chief prices current are :—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b. Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16., and boracic acid, £25., nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream, 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal tar and blast-furnace), 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 1½d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 2¼d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¾d.; ordinary sorts, 6½d. and 6¼d. (new season's contract prices), at Glasgow and other big centres; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42. and £40., less 2½% any port; saltcake, 40s. to 41s. 3d.; soda ash, £5. 10s. to £5. 15s., nett, Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d., prompt f.o.b. Leith; sulphate of copper, £26. 15s., less 5% Liverpool, prompt.

New Companies.

Central Acid Co., Ltd.—Capital £35,000., in £1. shares. This company has been formed to adopt an agreement with the Central Zinc Co., Ltd., and to carry on the business of sulphuric acid makers, manufacturing chemists, importers and manufacturers of and dealers in chemical, industrial and other articles, acids and compounds, etc. No initial public issue. The first directors are H. Ellison, F. Holroyd, H. W. Robinson and H. M. Ridge. During the continuance of the above mentioned agreement the Central Zinc Co., Ltd., may appoint one director when only three constitute the board; or two when such number is exceeded; qualification (except nominees of the said company) 500 shares.

Longwith By-Product Co., Ltd.—Capital £41,000., in £100. shares (400 participating preference). This company has been formed to adopt agreements (1) with the Sheepbridge Coal and Iron Co., Ltd., and (2) with the Power Gas Corporation, Ltd., to acquire land and erect thereon gas producer plant, by-products, recovery and chemical works, and to carry on the business of colliery owners, manufacturers of and dealers in gas, coke, fuel, bricks, tiles, pipes, pottery, terra-cotta, coal tar and other products (including by-products produced in the manufacture of gas or coke), etc. No initial public issue. So long as the Power Gas Corporation, Limited, and the Sheepbridge Coal and Iron Co., Limited, hold shares in this company they may each nominate two directors. No qualification necessary; remuneration £400. per annum, divided.

Matang (Perak) Rubber Syndicate Ltd.—Capital £12,500., in £1. shares. This company has been formed to adopt an agreement with F. McGillivray for the acquisition of two grants of land (adjoining) at Sungei Limau and Simpang, in the Matang District of the State of Perak, to clear and plant the same, or 500 acres thereof, with Para rubber or other product. Minimum cash subscription £6,000. The first directors are F. McGillivray, E. Cattanach, A. Russan and T. J. Ive; remuneration £150. per annum, divided.

Plaissetty Manufacturing Co., Ltd.—Capital £75,000., in £1. shares. This company has been formed to acquire from T. Terrell and J. P. H. Soper inventions in respect of incandescent filaments and mantles and burners for use in connection with mantles or lighting and patents and rights relating thereto, together with the business and assets of the Plaissetty Manufacturing Co., at Lewisham, to adopt an agreement with the said T. Terrell and J. H. P. Soper, and to carry on the business of manufacturers of and dealers in mantles, threads, filaments, silks and other materials or apparatus for incandescent lighting, lamps, gas fittings, etc. No initial public issue. The first directors are T. Terrell, J. P. H. Soper, A. O. Cudleigh and C. F. Hill; qualification £500; remuneration 2 guineas each per meeting attended. Registered office, 20, Copthall-avenue, E.C.

Strady Galvanising Co., Ltd.—Capital £30,000., in £1. shares. This company has been formed to carry on the business of galvanised sheet manufacturers, tin and terne plate makers, spelter manufacturers, steel makers and converters, ironmasters and founders, etc. No initial public issue. The first directors are M. S. Williams, M. O. Spence and R. Howells; qualification £1,000.; remuneration of chairman £100. per annum, to be increased to £300. when 10% dividend is paid; of other directors one guinea each per board meeting attended. Registered office, Marine-street, Llanelly.

LATE ADVERTISEMENTS.

EXPERIENCED Tar Distiller and Sulphate of Ammonia maker requires Situation; charge of small works preferred; best of references given.—"1,483," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

AS PARTNER.—An excellent opening occurs for a young man who has had experience in chemical works, preferably in the manufacture of SO_2 compounds (liquid), with a capital of £250., to take a half share in a business for the sale of patent plant which is in good demand. Office work and travelling.—Apply by letter, stating experience, "1,489," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

ENGLISHMAN (37) desires Appointment, corresponds French, German, Spanish, Portuguese; 15 years chemicals and soaps; 7 years Manchester shipping trade.—Address, "M 130," *Chemical Trade Journal* Office, 265 Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."

"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.

Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**

Half-Yearly (26 numbers) ..... **6s. 6d.**

Quarterly (13 numbers) ..... **3s. 6d.**

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisements intended for insertion in the current week's issue should reach the office by **Thursday morning** at the latest.

CURRENT TOPICS.

WORKMEN'S COMPENSATION.

THE Home Office report on proceedings taken under the Workmen's Compensation Acts of 1897 and 1900, and the Employers' Liability Act of 1880, during the year 1906 has now been issued. The information contained in the report is not complete, as neither the Workmen's Compensation Acts nor the Employers' Liability Act contain any provision for the making of returns to show the working of the systems of compensation which they established, and the only sources from which official statistics can be obtained, while supplying much valuable information, leave untouched the great body of cases of compensation to workmen. In the majority of cases, compensation is settled by agreement, no memorandum is registered, and therefore no official information is available.

The number of cases under the Workmen's Compensation Acts actually dealt with during the year in England and Wales by County Court judges and County Court arbitrators was 1,718; of these 1,404 were decided by judges, and 74 by a special arbitrator; 240 cases were settled by acceptance of money paid into court. In addition to the cases actually dealt with by County Court judges and County Court arbitrators, there were 814 cases which were either withdrawn, settled out of court, or otherwise disposed of in such a way as not to enable the officials of the Court to state definitely the results, making the total altogether of cases taken into court 2,552. From the time of the Acts coming into operation there has been a gradual increase in the number of cases—from 1,347 in 1899 to 2,532 in 1906.

Of the claims for compensation finally settled in 1906 within the cognisance of the courts, the decision in 1,179 cases was in favour of the applicant, and in 245 in favour of the respondent. The proportion of cases in which the applicant was successful was 83%, as compared with 82% in 1905 and 1904, and 84% in 1903. In 554 cases the compensation was awarded on account of death, and in all except one of them the deceased had left dependants. The number of cases in which compensation was awarded on account of death, and the total and average awards, were respectively as follows: 553, £105,454., £190. 13s. 11d. Since 1899 there has been a gradual increase, the figures in that year being—219, £37,904., £173. 1s. 7d. With regard to the grants of compensation for injury, there were 124 cases in which the compensation is returned as consisting of a lump sum, and 501 in which a weekly sum was assigned. In 17 of the cases in which a lump sum was paid the plaintiff accepted money paid into court. In the majority of the remainder a lump sum appears to have been awarded by consent of the parties. The average was £36. 3s. 11d. For cases of injury the average of the weekly sums assigned was—for total incapacity 11s. 6d., and for partial incapacity 9s. 10d.

Digitized by Google

A table gives the number of cases in which memoranda were registered in County Courts, and shows which cases were settled by agreement, which by committees representative of employers and employed, and which by an agreed arbitrator. The totals under these three heads were—by agreement 5,096, by committee 68, and by arbitrator 7; the corresponding figures for 1905 being—4,244, 62, and 11. The gross total, 5,171, shows a considerable increase on the figures for previous years—1,636 in 1901, 2,161 in 1902, 2,985 in 1903, 3,625 in 1904, 4,317 in 1905—but it still represents only a small proportion of the agreements under the Acts. The average compensation to dependants awarded in case of death and the average weekly payments awarded in case of incapacity, in cases of which memoranda have been registered under the Acts, were respectively £167. 9s. 7d. and 13s. 3d. The number of cases of incapacity in which the memorandum registered was for a lump sum and not a weekly payment was 1,564, as against 2,229 cases in which a weekly payment was agreed upon.

Under the Employers' Liability Act the total number of actions brought in 1906 was 476, against 481 in the previous year and 688 in 1897. The amount of damages awarded was £9,341., compared with £15,114. in 1897. The operation of the Workmen's Compensation Acts, it will be noticed, has had the effect of greatly diminishing the litigation under the Employers' Liability Act. The average amount of solicitors' costs was £23. 14s. 10d. under the Employers' Liability Act, and £13. 7s. 1d. under the Workmen's Compensation Acts.

The number of cases under the Workmen's Compensation Acts carried to the Court of Appeal in England was 57, or just over 2% of the cases that came before the County Courts. This is a decrease as compared with the figure for 1905 (97), which, however, showed a considerable increase as compared with previous years, the figures being 61 in 1901, 59 in 1902, 38 in 1903, and 34 in 1904.

During 1906 the number of cases taken into court under the Workmen's Compensation Acts in Scotland was 370, or 82.7 per million of population. The corresponding figure for England was 77.8 per million. On the other hand, under the Employers' Liability Act the amount of litigation still remains greater in Scotland, England having 476 cases or 14.6 cases per million of population, while Scotland has 155 or 34.7 per million of population. The average amount of compensation paid during 1906 in Scotland in cases of death where dependants were left was (*a*) as regards cases decided in the Sheriffs' Courts, £171. 15s. 10d.; (*b*) as regards cases in which memoranda were registered, £189. 10s. 2d. In cases of incapacity the corresponding figures were: (*i*) where compensation was a lump sum, £8. 7s. 5d. and £31. 12s. 9d. respectively; (*ii*) where it was a weekly payment, 10s. 10d. and 13s. 2d. respectively.

In Ireland the number of cases under the three Acts was 274, the average amount of compensation being—in cases of death where dependants were left, (*a*) as regards cases decided in the County Courts, £130. 14s. 9d.; (*b*) as regards cases in which memoranda were registered, £75. 13s. 5d. In cases of incapacity the corresponding figures were: (*i*) where compensation was a lump sum, £20. 12s. 9d. and £68. 18s. 5d. respectively; (*ii*) where it was a weekly payment, 9s. 3d. and 10s. 11d. respectively.

It is satisfactory to note that not more than 29% of the accidents occurring in England and Wales were taken before the Courts. The number of deaths from accidents in 1906 was 2,103, and only 636 cases came before the Courts. As regards claims for injury, there are no official figures of the number of persons injured whose injuries disable them for work for more than a fortnight, and the percentage of cases litigated cannot therefore be given. From the unofficial figures, however, which are available for certain industries, it seems probable that the number of cases taken into Court is less than 1% of the total number in which compensation is payable.

Taking the Board of Trade returns as to the numbers employed, and the average weekly earnings, the amount paid as compensation in 1906 works out at about 10s. 7d. per £100. of wages paid.

NITRATE OF SODA.

The August shipments to Europe were 85,200 tons, and the quantity "loading" on 1st inst. was 119,000 tons, against 84,332 and 152,000 tons respectively last year. The discrepancy between these figures and recent private cable estimates of 95,000 and 90,000 tons, respectively shipments and loadings, is of no importance, as the clearance of a few cargoes at the minor ports may have been overlooked, as frequently happens. The most interesting feature is the despatch of a steamer cargo of 6,500 tons to Egypt, already referred to in these columns. Last month's European deliveries having been 43,000 tons, against 50,120 tons in August, 1906, the "visible" supply comes out at 385,390 tons, compared with 363,370 tons a year ago. Stocks at ports are 138,940 tons, against 79,510 tons last year. The market in all positions is dull, but nominally firm, with a complete absence of business, the price on the West Coast for autumn shipment being about 4d. per quintal lower than at the corresponding date in 1906.

It might reasonably be inferred from the official statistics quoted in our last issue that the potential output of nitrate of soda in Chili is already ample, inasmuch as temporary scarcity of labour alone prevents the production of a million tons per annum more than the world actually consumes; this without taking into account new "oficinas" now building, with a collective capacity of many hundreds of thousands of tons. The Chilian Government, however, thinks otherwise, and it has decided to further foster the development of the industry by establishing a Mortgage Bank for the purpose of making advances to new producers. The recent attempt made in London to enlist British capital in the debentures of a Chilian nitrate company is said to have met with little success, and it remains to be seen whether a different result will be obtainable in Chili, where money is scarce at the present time.

It is interesting to note that, according to our French contemporary, *L'Engrais*, Norway alone is expected to produce this year 25,000 tons of artificial nitrate, 100,000 tons in 1910, and 200,000 tons in 1915. We quote this forecast with all due reserve.

One of the periodical spurts is taking place in nitrate shares, in anticipation of the magnificent dividends about to be declared by a few of the more favourably situated producing companies. *Vogue la galère!*

NITRATE.—As we go to press, advices report the August output in Chili as 160,960 tons, compared with 162,423 tons in the same month last year. Notwithstanding this remarkable result, stocks on the West Coast are still about 40,000 tons in excess of those at the corresponding date. Nitrate for early shipment is offered at 8s. 11½d. per quintal, f.o.b., against 9s. 4½d. at this time last year. The market is weak.

FACTORY AND WORKSHOP ACT, 1901.

REGULATIONS FOR THE MANUFACTURE AND USE OF DINITROBENZOL AND ANILIN.

THE following draft Regulations have been issued by the Home Secretary, for the manufacture of dinitrobenzol and anilin and the use of dinitrobenzol in the manufacture of explosives :—

Whereas the manufacture of nitro- and amido-derivatives of benzene, and the manufacture of explosives with use of dinitrobenzol or dinitrotoluol, have been certified in pursuance of Section 79 of the Factory and Workshop Act, 1901, to be dangerous ;

I hereby, in pursuance of the powers conferred on me by that Act, make the following Regulations, and direct that they shall apply to all factories and workshops in which the said manufactures are carried on.

Definitions.

"Employed" means employed in any process mentioned in the Schedules.

"Surgeon" means the Certifying Factory Surgeon of the District or a duly qualified medical practitioner appointed by written certificate of the Chief Inspector of Factories, which appointment shall be subject to such conditions as may be specified in that certificate.

"Suspension" means suspension by written certificate in the Health Register, signed by the Surgeon, from employment in any process mentioned in the Schedules.

Duties.

It shall be the duty of the occupier to observe Part I. of these Regulations.

It shall be the duty of all persons employed to observe Part II. of these Regulations.

Part I.—Duties of Occupiers.

(1.) Every vessel containing any substance named in Schedules A or B shall, if steam is passed into or around it, or if the temperature of the contents be at or above the temperature of boiling water, be covered in such a way that no steam or vapour shall be discharged into the open air at a less height than twenty feet above the heads of the workers.

In every room in which fumes from any substance named in Schedules A or B are evolved in the process of manufacture and are not removed as above, adequate through ventilation shall be maintained by a fan or other mechanical means.

(2.) No substance named in the Schedules shall be broken by hand in a crystallising pan, nor shall any liquor containing it be agitated by hand, except by means of an implement at least 6 feet long.

(3.) No substance named in the Schedules shall be crushed, ground, or mixed in the crystalline condition, and no cartridge filling shall be done, except with an efficient exhaust draught so arranged as to carry away the dust as near as possible to the point of origin.

(4.) Cartridges shall not be filled except by means of a suitable scoop.

(5.) Every drying stove shall be efficiently ventilated to the outside air in such manner that hot air from the stove shall not be drawn into any workroom.

No person shall be allowed to enter a stove to draw it until a free current of air has been passed through it.

(6.) A Health Register, containing the names of all persons employed, shall be kept in a form approved by the Chief Inspector of Factories.

(7.) No person shall be newly employed for more than a fortnight without a certificate of fitness granted after examination by the Surgeon by signed entry in the Health Register.

(8.) Every person employed shall be examined by the Surgeon once in each calendar month (or at such other intervals as may be prescribed in writing by the Chief Inspector of Factories) on a date of which due notice shall be given to all concerned.

(9.) The Surgeon shall have power of suspension as regards all persons employed, and no person after suspension shall be employed without written sanction from the Surgeon entered in the Health Register.

(10.) There shall be provided and maintained for the use of all persons employed—

(*a*) suitable overalls which shall be collected at the end of every day's work, and washed or renewed at least once every week ;

(*b*) a suitable meal room, separate from any room in which a process mentioned in the Schedules is carried on, unless the works are closed during meal hours ;

(*c*) a suitable cloakroom for clothing put off during working hours ;

(*d*) a suitable place, separate from the cloakroom and meal room, for the storage of the overalls ;

And for the use of all persons handling substances named in the Schedules :—

(*e*) india-rubber gloves, which shall be collected, examined, and cleansed at the close of the day's work, and shall be repaired or renewed when defective, or other equivalent protection for the hands against contact ;

And for the use of all persons employed in processes mentioned in Schedule A :—

(*f*) clogs or other suitable protective footwear.

(11.) There shall be provided and maintained in a cleanly state and in good repair for the use of all persons employed :—

A lavatory under cover, with a sufficient supply of clean towels, renewed daily, and of soap and nail brushes, and with either :—

(*a*) a trough with a smooth impervious surface, fitted with a waste pipe without plug, and of such length as to allow at least two feet for every five such persons, and having a constant supply of warm water from taps or jets above the trough at intervals of not more than two feet ; or

(*b*) at least one lavatory basin for every five such persons, fitted with a waste pipe and plug or placed in a trough having a waste pipe, and having either a constant supply of hot and cold water or warm water laid on, or (if a constant supply of heated water be not reasonably practicable) a constant supply of cold water laid on and a supply of hot water always at hand when required for use by persons employed.

And for the use of all persons employed in processes mentioned in Schedules A and B :—

sufficient and suitable bath accommodation (douche or other), with hot and cold water laid on and a sufficient supply of soap and towels.

(12.) No person shall be allowed to introduce, keep, prepare, or partake of any food, drink, or tobacco in any room in which a process mentioned in the Schedules is carried on.

Part II.—Duties of Persons Employed.

(13.) Every person employed shall :—

(*a*) present himself at the appointed time for examination by the Surgeon as provided in Regulation 8 ;

(*b*) wear the overalls provided under Regulation 10 (*a*), and deposit such overalls, and clothing put off during working hours, in the places provided under Regulation 10 (*c*) and (*d*) ;

(*c*) use the protective appliances supplied in respect of any process in which he is engaged ;

(*d*) carefully clean the hands before partaking of any food or leaving the premises ;

(*e*) take a bath at the factory at least once a week, and when the materials mentioned in the Schedules have been spilt on the clothing so as to wet the skin.

Provided that (*e*) shall not apply to persons employed in processes mentioned in Schedule C.

(14.) No person employed shall :—

(*a*) after suspension, work in any process mentioned in the Schedules without written sanction from the Surgeon entered in the Health Register ;

(*b*) introduce, keep, prepare, or partake of any food, drink, or tobacco, in any room in which a process mentioned in the Schedules is carried on ;

(*c*) break by hand in a crystallising pan any substance named in the Schedules, or agitate any liquor containing it by hand, except by means of an implement at least 6 feet long ;

(*d*) interfere in any way, without the concurrence of the occupier or manager, with the means and appliances provided for the removal of the fumes and dust, and for the carrying out of these Regulations.

Schedules.

(A) Processes in the manufacture of :—Nitrobenzol, Nitrotoluol, Dinitrobenzol, Dinitrotoluol, Trinitrotoluol, Paranitrochlorbenzol.

(B) Processes in the manufacture of :—Anilin oil, Anilin hydrochloride.

(C) Any process in the manufacture of explosives with use of dinitrobenzol or dinitrotoluol.

ALCOHOL FOR INDUSTRIAL PURPOSES.

THE annual report of the Commissioners of Inland Revenue contains the following references to the new regulations with regard to industrial alcohol, which came in force on October 1st, 1906.

(1.) A new variety of methylated spirit, to which the name of industrial methylated spirit was given, was authorised for use solely in arts and manufactures. It takes the place of that previously known as ordinary methylated spirit, and is required to contain only half the proportion of the denaturant which was present in the ordinary spirit. The relative compositions are :—

Industrial methylated spirit—alcohol, 95 parts, wood naphtha, 5 parts; ordinary methylated spirit—alcohol, 90 parts, wood naphtha, 10 parts.

The composition of the methylated spirit allowed to be sold to the public generally for domestic and other purposes has not been altered; this spirit is known as mineralised methylated spirit, and contains the same proportion of wood naphtha as was required in the ordinary methylated spirit above referred to, with the addition of a small proportion of mineral naphtha.

(2.) The payment was authorised of an allowance on all spirits used by an authorised methylator for making industrial methylated spirit, and on all spirits, except foreign methylic alcohol, received by any person for use in any art or manufacture under section 8 of the Finance Act, 1902. The allowance is the same as that which is paid upon plain British spirits exported—viz., 3d. per proof gallon, which is the estimated cost to the distiller of the revenue restrictions on the manufacture of spirits. It is paid in the one case direct to the authorised methylator, and in the other to the authorised user.

(3.) Foreign methylic alcohol may now be received and used under section 8 of the Finance Act, 1902, without payment of the differential duty payable on foreign spirits.

(4.) Under section 8 of the Finance Act, 1902, any person allowed to receive spirit in a pure state duty free for use in any art or manufacture was required to pay the expenses incurred in placing an officer in charge of his premises to supervise the use of the spirit. The Act of 1906 authorised relief from this payment unless special attendances of the officer to suit the convenience of the user are required.

(5.) Under the previous law the *maximum* quantity of methylated spirit which a licensed retailer could keep in stock was 50 gallons, and the *maximum* quantity he could sell at one time was 1 gallon. This limitation was repealed, and power was given to the Commissioners to fix the limit by regulation, which has been done by increasing them to 200 and 4 gallons respectively.

The effect of alterations (1) and (2) has been largely to reduce the initial cost of methylated spirit used for industrial purposes, and to provide for use by manufacturers and others a spirit purer than was previously available, and consequently better suited for many purposes for which spirit is required. There is good reason to believe that the industrial purposes are relatively few, of which the requirements in respect of alcohol cannot be satisfactorily met by the use of industrial methylated spirit, and in future it is probable that the cases which will require to be dealt with under the provisions of section 8 of the Finance Act, 1902, will not be numerous.

The purer character of the new variety of methylated spirit undoubtedly exposes the revenue to greater risk than was the case with ordinary methylated spirit. It was felt, however, that if users of industrial methylated spirit were not to be deprived of much of the benefit of the new arrangements it was necessary to avoid making the restrictions on its use too stringent; and accordingly applications for permission to receive such spirit, which have been very numerous, have been dealt with as liberally as possible, and the conditions which have been drawn up to govern generally the receipt and use of the spirit have been made as few and as simple as is consistent with adequate protection against abuse.

New Russian Albumen Factories.—The Ekaterinburg Town Council has decided to construct an albumen factory for the purpose of using the refuse of the town slaughterhouses, and the necessary funds have been set aside for it. It is expected that at an early date the towns of Perm and Tinnen will follow the example of Ekaterinburg. Hitherto the waste has been destroyed by fire, at considerable expense.

TIN MINING IN THE FEDERATED MALAY STATES.

THE following particulars of the tin mining industries of the Federated Malay States are taken from the annual report for 1906 of the Resident-General (Sir W. Taylor, K.C.M.G.).

The Senior Warden of Mines, in his report on the working of the Mines Department, states that the mining revenue derived from all sources was 10,588,824 dols., as compared with 9,689,501 dols. in 1905. Of the increase of 899,323 dols. the export duty on tin (10,036,796 dols.) is responsible for 787,169 dols., and premia on mining leases 102,049 dols.

This increased duty was collected from a smaller quantity than in the preceding year, the output for 1906 having receded to 816,786 pikuls, a decrease as compared with the output of 1905 of 39,874 pikuls. The decrease of 39,874 pikuls was made up of 1,540 pikuls of block tin and 38,333 pikuls of tin ore, the output of 816,786 pikuls having consisted of 306,748 pikuls of block tin and 510,038 pikuls of tin ore. The average local sterling value was £175. 12s. 3d. a ton, as compared with £138. 10s. 5d. in 1905.

While the area of mining land increased by 6,285 acres, and large profits were realised on the tin produced in 1906, the output in all four States shows a falling-off. In respect of Perak and Pahang an explanation of a satisfactory nature is forthcoming. In Negri Sembilan the outlook is not promising, and a decreased output appears not unlikely.

The Senior Warden is of opinion that the year 1906 was a satisfactory one for tin miners. Though the output decreased, the value of the tin produced increased by some 4,000,000 dols., and extensive building operations were going on at all the principal mining centres, mainly from the profits realised by the industry.—*Board of Trade Journal.*

THE ROUMANIAN PETROLEUM INDUSTRY.

ACCORDING to the *Roumania Economica* the amount of crude oil produced in Roumania during the first six months of 1907 was 562,451,000 kilogs. as compared with 409,511,000 kilogs. in the corresponding period of 1906.

The following table (reproduced from the *Board of Trade Journal*) shows the exports of petroleum from 1st January to 30th June in each of the years 1906 and 1907 :—

	First six months.	
	1906. Kilogs.	1907. Kilogs.
Petroleum, unrefined ..	12,732,126	19,818,557
,, refined	100,055,163	114,533,003
Benzine	34,026,089	49,433,345
Mineral oil	4,411,165	11,672,602
Total	151,224,543	195,457,507

Will.—The late Sir William Henry Perkin left estate valued at £78,611.

Liverpool Tropical Products Exhibition.—On Monday week, at a meeting of the committee of the Liverpool Tropical Products Exhibition, which will be opened next month during the visit of the Chambers of Commerce, Sir Alfred Jones spoke of the advantages which would accure to the trade of Liverpool and to that of the country and Empire if a permanent exhibition of this nature were established. He heard that it was the intention to establish a permanent exhibition in London, and therefore Liverpool could not be behindhand in this matter. Mr. Haldane had arranged to open the exhibition on one of the days. Sir Alfred Jones strongly advocated the erection of mills and factories in Liverpool, thereby providing means of dealing with the material imported. If this were done the trade of the port would not have the same chance of shifting as at present. Mr. John Holt also spoke of the necessity for more enterprise on the part of the millers of Liverpool. There was no reason why there should not be ground-nut mills in Liverpool, the oil being used for margarine purposes. If they had the milling enterprise in Liverpool and the necessary capital, they would be able to compete with the margarine industry in Holland. These views were endorsed by Sir Alfred Jones, who said he would be glad to take one-fourth part in any scheme which the merchants of Liverpool might start in ground-nut mills.

INDUSTRIAL POISONING.

THE subject of industrial poisoning is dealt with at length in the annual report of the Chief Inspector of Factories and Workshops for 1906. We give below an abstract of the remarks of the Superintending Inspectors for the various Divisions.

SOUTHERN DIVISION.

The number of cases of lead poisoning reported in 1906 was 278; mercurial poisoning, 6; phosphorus poisoning, 1; arsenical poisoning, 2.

Lead Poisoning.—Mr. Pendock (Bristol).—Serious cases occurred at a lead works which recently opened for the purpose of smelting and refining the residue from previous workings. Safeguards are being considered to prevent the escape of fumes from the slag hole; at present, owing to a percentage of iron ore being used in the furnace to assist the process, the acidity of which gradually enlarges the slag orifice, the fumes are emitted in considerable quantity towards the end of every fortnight's run. If this enlargement cannot be checked, it will be necessary to provide some means for exhaust ventilation connected with a fan. Another probable cause for the undue escape of fumes is to be found in a certain amount of back pressure set up in the cupola through choking of the outlet flues, which appear to be smaller in area and shorter in length than is the practice of construction elsewhere; the actual dimensions being five feet six inches by four feet three inches, and 300 yards in length. A deposit of ten inches on the floor of the flue reduces its capacity by 25% or more, and this is a matter to which the manager is giving consideration. It is intended to instal warm shower baths instead of the present hip baths.

Mercurial Poisoning.—Mr. Younger (Bristol).—I investigated (in the South London District) a case of slight mercurial poisoning at a factory at which electrical meters were manufactured. The work to which the poisoning was attributed was the filling of meter baths with metallic mercury. The precautions taken at this factory, at which mercury was also used for calibrating electrolytic meters, &c., appeared to be adequate. The ventilation and washing conveniences were satisfactory, a mess room was provided, and the taking of meals in work rooms prohibited, and each man was furnished with a tooth-brush and mouth wash consisting of a solution of chlorate of potash.

Mr. Gailey (South London).—Two slight cases of mercury poisoning were reported from a factory in which mercury is used in the manufacture of electrolytic meters, and another case was reported from a factory in which chemicals were manufactured.

Phosphorus Poisoning (Necrosis).—Mr. Pendock (Bristol).—The only case of necrosis was that of a man 56 years of age who had been employed practically all his life in match making with various firms. After serving for about 13 years in Ireland in the mixing and boxing departments he came back to this district, entering into the employ of a firm of match makers in a general labouring capacity. Here he met with an accident of trivial cause which broke his leg, and owing to the difficulty experienced in setting it he underwent various operations and treatment at the infirmary until the whole of the leg had been amputated. Thus crippled and impoverished, he again asked work of the firm; and, as he could only move about with difficulty, he was given what was considered an easy job for him at one of the dipping machines. His duty was to sit up close to the revolving dipping slab and pick from it by means of a long toasting fork all the stray sprints that found their way into the paste. The dipping slab was covered with a large hood connected with a powerful exhaust fan, as also was the adjoining pan of composition from which the slab was replenished. The front part of the large hood consisted of a glazed window, and in order that he could sit rather closer to the machine and so avoid the trolleys and other traffic continually passing behind him, a notch had been cut in the window to admit of a little more freedom for his arm. As the patient sat so closely to the machine, and so continuously, he did not get that temporary relief and freedom from the fumes which an ordinary and more active attendant would have got. Moreover, as he was a man who could take no exercise except the brief walk to his house, his general health became so impaired that he might be characterised as a "bad subject." He also admits being an inveterate chewer of tobacco. The case is described as one of moderate severity only, however, and it is hoped that further progress of the disease will soon be arrested.

Carbon Monoxide Poisoning.—The Inspectors have been under instructions concerning the danger of carbon monoxide poisoning—increased by the growing use of producer gas, Mond gas, etc. They have issued the Home Office Memorandum upon the subject where necessary, and have endeavoured to obtain the adoption of the precautions described. The only reports of poisoning received are quoted below.

Mr. Ireland (Norwich).—One case of carbon monoxide poisoning was due to an escape of water gas in an engine house in which the power was derived from Dowson gas. A water seal has been provided to prevent a recurrence, and I advised the provision of an oxygen cylinder.

Mr. Gailey (South London).—Respecting a fatal accident which occurred to a night watchman by his falling down a shaft leading to a tunnel in which a sewer was being constructed, the medical evidence showed that the deceased had been poisoned by carbonic oxide and carbonic acid. These oxides of carbon in all probability made him giddy and caused him to stumble, and they appear to have been given off by the coke fire which the deceased had placed in front of his hut.

Mr. Pendock (Bristol).—One fatal case of poisoning by carbon monoxide occurred to a man employed in feeding the blast furnace at an iron works, on Sunday morning at a period when he happened to be practically alone, and, although a fairly experienced man, he is supposed to have used some indiscretion in connection with his work. He probably either failed to fire the gases after charging the furnace or neglected to get to the windward side of the furnace opening while the gases were still escaping. He was found unconscious, although within a short time previously he had been seen in full activity; all artificial means that could be resorted to were unavailing. A copy of the memorandum on water gas has been sent to the firm, and every attention is promised by them to prevent recurrence of such a fatality.

(To be continued.)

A REMARKABLE OIL PIPE LINE.—The Southern Pacific Company has contracted for the construction of an oil pipe line which, according to the *Iron Age*, has several novel characteristics. The pipe is for carrying a very heavy and viscous oil from the Kern River (California) oil-fields to the sea board, a distance of 285 miles. The oil being exceedingly thick, it was found necessary to devise a method for causing it to flow through the pipe. Experiments were made on small sizes of pipe through which a mixture of oil and water was allowed to flow. By twisting the pipe a rotary motion was imparted to the fluid, and the water, being the heavier of the two liquids, surrounded the oil, and thereby reduced the co-efficient of friction. Another experiment, to determine the necessary twist to give to the pipe, was made by placing the mixture in a glass bottle which was then put into a lathe. By revolving it the *minimum* speed at which the water completely encompassed the oil was found. The pipe line as constructed is 8in. diameter, and it has six spiral indentations 0.125in. deep. The first section of 31 miles has been in operation for several months, and the complete length will require 23 pumping stations located along the line. The estimated capacity of the pipe is 23,000 barrels of heavy oil in 24 hours.

LAWES' CHEMICAL MANURE CO.—Mr. E. G. Cubitt, who presided at the annual meeting of shareholders on Tuesday, said they were putting aside £1,000. to a reserve fund, and during the year they had paid off £25,000. of the redeemable debentures. The consequential shrinking in the capital of the company was met to a certain extent by the reserve fund, which was invested in the business. A higher dividend would be paid. There had been during the year a rise in the prices they obtained, but, on the other hand, there had been an unprecedentedly sharp rise in the prices of raw materials. Arsenic entered largely into the composition of some of their dips. When he first joined the Board arsenic could be bought for between £11. and £12. a ton, but lately the price had been somewhere round £35. The price of sheep dips, however, instead of rising, had a tendency to go the other way. The lease of the old works at Deptford, lately used as a depot, expired in 1911, but neighbouring landholders were willing to take the site at once, and the directors thought it advisable to accept the offer. They hoped that would effect a saving in expenses. At Barking the company had more land than it required, and a small portion had been sold. For some of the minor machinery electric power had been installed. That would undoubtedly increase the efficiency and convenience of the works, and he hoped it would result in a saving of working cost. The Australian market was failing them, as Australia was making its own chemical manure, and they would have to find a fresh market for some of their stuff.—The report was adopted, and a dividend of 7s. 6d. upon the ordinary shares was declared.

Analytical Notes.

THE CONSTITUTION OF AMMONIACAL LIQUORS.*

(*Concluded from p.* 197.)

MR. LINDER'S MEMORANDUM.

Appendix.

Estimation of CO_2, H_2S, and HCy in Saturator Gases.

A. *Gases Hot.—Apparatus :* Litre separating cylinder, jacketed with flannel, provided at end A with wide-bore stopcock, at B with ground-in stopper; actual volume determined by water measurement. Fill the cylinder with water and place vertically; connect upper end A to flue by wide-bore tubing; remove the stopper and run out the water. When heated to flue temperature by issuing gases, close B and cool the cylinder cautiously with water, keeping A open. Steam will thus be condensed and more gases drawn in, the cylinder finally containing 20 to 30 c.c. of condensed liquor in contact with cold permanent gases at flue pressure.

Analysis of Sample.—Admit to the cylinder 50 c.c. of 2.5 normal ammonia, shake thoroughly; open A and destroy the vacuum, then reshake with A closed, repeating the operation until air ceases to enter on opening the stopcock, showing that absorption is complete. Run the solution into 500 c.c. flask, wash out with distilled water, and make up to 500 c.c. Proceed as follows :—

(1.) *Carbonic Acid.*—50 c.c. of liquor, 250 c.c. water, and 10 c.c. of ammoniacal calcium chloride (25%) are heated in Erlenmeyer flask provided with Bunsen rubber valve to a temperature of 98° C. for 1 to 1½ hours—heating is best effected by partial immersion of the flask in a water bath, but if this be inconvenient, it is sufficient to allow steam to freely play on the bottom—it is not advisable to use a direct flame. Filter, wash three times with boiling water, boiling for a minute each time before decanting. Pierce the paper and wash back traces of adhering precipitate into the flask, dry the paper on a clock glass, incinerate as far as possible on platinum wire and drop the ash into the flask. Add 25 to 30 c.c. of water and a drop of methyl orange, then run in $\frac{N}{2}$ HCl in slight excess with constant shaking,† and bring back with $\frac{N}{2}$ Na_2CO_3. Then,

1 c.c. $\frac{N}{2}$ HCl = 0.011 gram. CO_2 = 5.6 c.c. (0° C. 760 mm.).

(2.) *Sulphide* (H_2S).—As thiosulphate is never present in other than traces, the sulphide may be determined by direct titration with $\frac{N}{10}$ iodine in the usual way. It is more accurate to run the sulphide solution into slight excess of $\frac{N}{10}$ iodine acidified with sulphuric acid, and bring back with thiosulphate—starch indicator.

1 c.c. $\frac{N}{10}$ iodine = 0.0017 gram. H_2S = 1.12 c.c. (0° C. 760 mm.)

(3.) *Cyanide* (HCy).‡—As traces of thiocyanate are formed by interaction of dissolved oxygen on sulphide and cyanide, Feld's method of distillation with lead nitrate cannot be applied.

Proceed by polysulphide method as already described.

1 c.c. $\frac{N}{10}$ $AgNO_3$ = 0.0027 gram. HCy = 2.24 c.c. (0° C. 760 mm.)

Example :—Total volume of solution 500 c.c.

CO_2 .. .. 25 c.c. of the above required 9.8 $\frac{N}{2}$ HCl

= 9.8 × 0.011 × 20 = 2.156 grams.
= 9.8 × 5.6 × 20 = 1,098 c.c.

H_2S .. .. 25 c.c. of the above required 19.30 $\frac{N}{10}$ I

= 19.3 × 0.0017 × 20 = 0.6562 grms.
= 19.3 × 1.12 × 20 = 432 c.c.

HCy .. .. 50 c.c. of the above required 5.07 $\frac{N}{10}$ $AgNO_3$

= 5.07 × 0.0027 × 10 = 137 gram.
= 5.07 × 2.24 × 10 = 114 c.c.

Whence,

CO_2	= 1098	= 66.8 per 100 vols. of dry saturator gases.
H_2S	= 432	= 26.3
HCY	= 114	= 6.9
	1,644	100.0

A. *Cold Gases.*—This method is applicable for gases that deposit no appreciable amount of moisture on cooling to air temperature. It has been successfully applied to gases at 80° F.

Apparatus.—For estimation of CO_2 + HCy, H_2S, and residual nitrogen, a Bunte burette, graduated in c.c. throughout, with levelling cylinder containing distilled water at approximately air temperature :—

(1.) The volume of gas is rapidly read off at air temperature and pressure, water is then removed from below the gas by gentle suction, leaving the burette full of gas at reduced pressure.

Volume of gas taken :—100 c.c. moist, at air temperature and pressure = CO_2 + HCy + H_2S + nitrogen.

(2.) Admit 10 c.c. of 2.5 normal potash (or ammonia) followed by distilled water.

Contraction = CO_2 + HCy + H_2S.

Residual gas taken to be nitrogen.

(3.) Determine sulphide by the method described above.

1 c.c. $\frac{N}{10}$ iodine = 1.12 c.c. H_2S (0° C. 760 mm.).

Multiply by suitable factor to reduce volume to air temperature and pressure (moist), and reach the figure for CO_2 + HCy by difference.

For estimation of HCy use a litre cylinder, jacketed with felt or corrugated paper, as described above. Fill the cylinder with distilled water, admit gas from the flue by allowing the cylinder to rapidly empty and pass the gas through the cylinder for two to three minutes to allow of drainage; the temperature is meanwhile read off by inserting a thermometer through the open end; it should approximate to that of the atmosphere. Close the exit, then the stopcock at inlet end. Detach from flue and momentarily turn the stopcock to reduce the pressure to atmospheric. Admit 50 c.c. 2.5 normal ammonia and proceed as described in method A above. Make solution up to 250 c.c.

Analysis of Sample :—

(1.) H_2S - - - 25 c.c. is run into excess of $\frac{N}{10}$ iodine acidified with sulphuric acid and brought back with $\frac{N}{10}$ thiosulphate as described above.

1 c.c. $\frac{N}{10}$ iodine = 1.12 c.c. H_2S (0° C. 760 mm.).

(2.) HCy - - - 50 c.c. is treated with polysulphide, and the thiocyanate estimated as described above.

1 c.c. $\frac{N}{10}$ silver nitrate = 2.24 c.c. HCy (0° 760 mm.).

Calculation :—Reduce the total volume of gas collected to 0° C. 760 mm. and calculate the volumes of H_2S and HCy found to 100 volumes. Combine the various results as indicated.

THE ANALYSIS OF PRODUCER GAS FOR THE POWER ENGINEER.

BY H. PROCTOR SMITH, F.C.S.*

In the writer's opinion there is nearly always a gap between the results given by a chemist and the data required by an engineer to act upon the information given, and, as a rule, this gap can be filled much more easily by the chemist than by the engineer, and if it *were* filled by the mutual co-operation of the chemist and the engineer there is no doubt that valuable information would be acquired, and would eventually bring the chemist and the engineer to be recognised as main factors in helping to swell the profits of an industrial concern, and not as at present mere "non-producers" and a necessary nuisance.

This is illustrated in a very striking manner since the rapid advances which have been made in utilising producer gas as a motive-power in a gas engine.

In this instance we have a chemist who makes analyses of samples of the gas, and perhaps offers suggestions as to the reason for an increased percentage of carbon dioxide, or of hydrogen, and so forth, and who reports to the engineer the relative quantities of carbon dioxide, carbon monoxide, hydrogen, marsh gas, etc., but, as a rule, this is all.

Now, the engineer knows that he wants a gas with as large an amount of combustible as possible, and also knows that the gases, carbon monoxide, hydrogen, and marsh gas are combustible, but from looking at the mere percentages of these gases he cannot, as a rule, form much idea of the amount of horse-

* From the 43rd Annual Report on Alkali, etc., Works, by the Chief Inspector.

† Mr. Young informs me that time is saved if excess of acid (1 to 2 c.c. $\frac{N}{2}$) be run in at once and the solution heated to boiling to dissolve the precipitate: it is then cooled and brought back with half-normal alkali.

‡ In one case ferrocyanide was obtained in the test solution in addition to cyanide and thiocyanate; this was traced to interaction between cyanide, alkali absorbent added, and iron salts primed over from the saturator bath. The ferrocyanide formed was small in absolute amount, but large when calculated as a percentage figure on the total cyanogen present, and testing at the saturator exit had, in consequence, to be abandoned.

* In the *Chemical News*.

Digitized by Google

power which this gas will develop in his engine, and the factors given below are such as will enable either the engineer or the chemist to rapidly convert the gas analysis into a heat analysis, and from that to a power analysis.

The power capable of being developed by a gas is a ratio of its heating value, and this value is in relation to the amounts of its constituent gases. An element when combining with oxygen evolves a certain definite amount of heat, and, if this change is brought about rapidly, also light, when the process is termed "combustion."

With the commoner elements—carbon and hydrogen—use is made of this reaction to generate heat, and the elements are termed *fuels*. Coal is a mineral consisting chiefly of carbon and hydrogen, and may be ignited and burnt in air with the generation of heat. Coal may also be partially burnt in a closed vessel termed a "gas producer," and converted into gas which may be burnt and converted into power apart from the vessel in which the gas is generated.

The amount of heat so generated is expressed in two chief units, viz. :—

British Thermal Unit (B.T.U.), which is the amount of heat required to raise 1 lb. of water 1° F. ;

Kilogramme Calorie, which is the amount of heat required to raise 1 kilogramme of water 1° C.

The water in each case being at its point of maximum density, 39.2° F. or 4° C.

The heating or calorific value of carbon is 14,544 B.T.U. ; that is to say, if 1 lb. of carbon was burnt in oxygen or air it would generate enough heat to raise 14,544 lbs. of water 1° F.

To consider now the combustible gases :—

	B.T.U. per lb.
Carbon monoxide	4,386
Hydrogen	61,524
Marsh gas	24,021

That is, the heat generated from the above gases in *parts by weight* ; but as we generally measure gas these figures require to be converted into the B.T.U. or calories which are developed by burning 1 cubic foot or 1 cubic metre of the gas.

Further, in burning all substances containing hydrogen the combustion produces water, and if, as is generally the case, the final temperature is above 212° F., that water is converted into vapour (steam) and passes off in the waste gases. Now, the conversion of water at 212° F. into steam at 212° F. absorbs a large amount of heat termed "latent heat," which can only be recovered by condensing the steam, and thus the *available* calorific value produced by burning hydrogen is lowered, and therefore in all compounds containing hydrogen we have a *total* and an *available* calorific value.

The following factors serve to convert any of the gases, hydrogen, carbon monoxide, or marsh gas, directly into terms either B.T.U.'s or calories :—

	B.T.U per cubic foot		Kilogrm. Calories per cubic metre.	
	Total.	Avai'able.	Total.	Available.
Carbon monoxide	3.419	3.419	30.43	30.43
Hydrogen	3.473	2.924	30.91	26.026
Marsh gas	11.278	10.133	100.38	90.225

To convert { Calories per cubic metre into B.T.U. per cubic foot multiply by 0.11235. / B.T.U. to calories multiply by 0.252. / Calories to B.T.U. multiply by 3.968.

To show how such a calculation may be worked, suppose we have a sample of Mond gas of the following composition :—

	Per cent.		B.T.U. per cubic foot. Total.	Actual
Carbon dioxide..	12.9 ×	—	Nil	Nil
Carbon monoxide	13.2 ×	3.419	45.14	45.14
Hydrogen	24.8 ×	3.473 or 2.924	86.13	72.51
Marsh gas	2.3 ×	11.278 or 10.133	25.94	23.30
Nitrogen	46.8 ×	—	Nil	Nil
	100.0		157.21	140.95

Thus, by a few very simple calculations it is possible to convert a chemical analysis into a heat analysis.

Then for power conversion :—

1 B.T.U. = 778 foot-lbs.

1 Horse-power = 33,000 foot-lbs.

Thus, the *theoretical* power analysis is merely a matter of proportion.

It must, however, be borne in mind that the theoretical and practical results, otherwise the efficiency of the best heat engine of this type, seldom exceeds 25 per cent., but to the gas-power engineer the calorific power rather than the chemical analysis of a gas is what is required.

Trade Notes.

THE SICILIAN SULPHUR INDUSTRY.—The British Consul at Palermo reports that the sulphur industry is now passing through another crisis, the Bank of Sicily having refused to continue making advances on Sulphur Deposit Notes except at three-fifths value instead of four-fifths, as it had hitherto been paying. The Bank has already advanced over £400,000. on such notes. "Owing to this," he continues, "some of the sulphur mines have had to stop working. Telegrams are being sent to Rome to bring pressure to bear on the Government to induce the bank to continue issuing advances. The matter is said to have been under consideration at the Council of Ministers, and an inspector has been sent to make an inquiry. The "Consorzio," which was instituted on the termination of the Anglo-Sicilian Company, collects all the sulphur produced, and the producers receive a certificate for the amount deposited, by which they obtain a part of the value represented. Advances on the value are made by the Bank, which allocated a sum of ten million lire for this purpose. The production is now in excess of the world's demand, owing to the amount of American sulphur produced from Louisiana. The Bank's advances have reached the limit of ten million lire, and only a portion of the sulphur has been sold.

ARTIFICIAL INDIGO.—The *Manchester Guardian* says :—"According to the statistics just published, Germany exported artificial indigo to the value of 31.6 million marks during the past year, against 25.7 million marks in 1905, 21.7 million in 1904, and 7.6 million in 1898. The largest importer of this product was Japan, taking 6.9 million marks. China imported it to the value of 5.3 million marks, the United States 4.5 million marks, Russia 3 million marks, Austria-Hungary 2.7 million marks, Great Britain 2.6 million marks, the other principal importers being Holland, France and Italy. During the past year there has been a slight improvement in the price of the artificial product, due chiefly to the agreement between the Badische Company and Meister, Lucius and Brüning. In 1895 Germany imported natural indigo to the value of 21.5 million marks ; in 1898 this had sunk to 8.3 million marks, whilst last year only 800,000 marks' worth was imported."

COTTONSEED OIL EXTRACTION.—The Acting British Consul at Savannah (Mr. A. Harkness) reports that he has received information from Atlanta, Georgia, to the effect that the State Chemist has completed a chemical demonstration in the analysis of cottonseed meal which it is thought will be of interest to dealers and farmers, as it bids fair to change greatly the present method of extracting oil from cottonseed. Instead of applying the usual tests of such experiments, that of using ether mixed with cottonseed meal, he applied carbon tetrachloride, which is much less expensive, and found upon analysis that the weight of the oil extracted by this process was greater than by ether, and far less costly. This question has been the subject of tests also by the State Chemist of Mississippi, who is said to have obtained similarly successful results and who is a supporter of the theory that by its use more oil will be extracted from the seed. It is estimated that under the present system, at least 10% of the oil is left in the meal, and as this oil is useless as a fertiliser, most of it is lost.

ROUMANIAN PETROLEUM.—The *Manchester Guardian* says :—The increasing importance of the Roumanian petroleum field is shown by the fact that 195,060 tons of petroleum were exported during the first half of the present year, against 151,316 tons during the corresponding period last year, and 85,835 tons during the first six months of 1905. The principal consumers were France, which took 61,823 tons ; England, 54,649 tons ; Germany, 30,598 tons ; Austria-Hungary, 10,483 tons ; India, 15,083 tons ; and Turkey, 14,101 tons. Of the total amount exported France took 31½% (against 33% in 1906, 65½% in 1905, and 22½% in 1904), England 23% (against 20% in 1906, 7½% in 1905, and 22½% in 1904), Germany 16% (against 16% in 1906, 14½% in 1905, and 20% in 1904), Italy 2½% (against 8% in 1906 and 7% in 1905), Turkey 7% (against 7½% in 1906, ½% in 1905, and 1½% in 1904), and Austria-Hungary 5½% (against 5% in 1906, 10½% in 1905, and 12½% in 1904).

Continental Notes.

THE *Chemiker-Zeitung* for August 7 contains a description of an ingenious machine for moistening and mixing finely-ground tanning materials. The difficulty of accomplishing this object without causing the material to collect into lumps or balls is overcome by subjecting it to violent motion. The uniform blending of tanning matters is becoming more and more important as the number in common use increases, for different tanning agents produce very different results as regards colour and quality of leather, and the tanner is very often obliged to use mixtures in order to produce the desired effect. The inventor of the machine is A. F. Diehl, of Munich.

In the same issue, P. Pastrovich gives the results of the examination and analysis of the fat extracted from the seeds of *Canarium commune L.*

In the number for August 10, Dr. A. Frank-Kamenetzky writes on the use of the immersion refractometer in distillery practice. By taking the specific gravity of a mash, and also the refractive index, it is possible to arrive at the percentage of alcohol and the extract without making an actual analysis. In order to make it easier to convert the readings of the saccharometer and the refractometer into percentage composition the author has devised a slide rule, so that it is possible to determine these two important constituents of distillery liquids in a very short time. A large number of examples are given to show the close agreement with the figures obtained by the usual methods of analysis.

The proximate composition of cottonseed oil forms the subject of a communication by V. J. Meyer. In order to ascertain what are the fatty acids present in this oil, he converted them into the methyl esters by treatment with methyl alcohol and hydrochloric acid. The mixed esters were then subjected to fractional distillation *in vacuò*, and from the boiling-point, melting-point, iodine value, and other characteristics of the fractions, conclusions were drawn as to the substances composing them. It was found that about 70% of the cottonseed oil consisted of palmitin, but indications were also found of the presence of stearic and arachinic acids.

S. Kohn writes upon the analysis of sodium silicofluorate. The method he adopts depends on the precipitation of the fluorine and the silica by the addition of a neutral solution of calcium chloride and the titration of the resulting acid solution with standard caustic soda solution. The principal difficulty was to find an indicator that would give a satisfactory end-point, but the author claims to have found one in alizarine, which changes from yellow to violet.

Of the products of the artificial industry, few are more important than the artificial hair that is now being manufactured at several different works. In a paper in the *Chemiker-Zeitung* for August 14, W. Massot gives descriptions and micro-photographs of horse hair made by four different processes, and also samples of artificial straw, and human hair used for making wigs.

In the same issue Dr. E. H. Schultze adversely criticises the German custom of valuing fertilisers according to the amount of phosphoric acid soluble in water, instead of basing their opinions as to efficacy upon the determination of the phosphoric acid soluble in citric acid solution. One effect of the German method is that the manufacturers often make phosphates containing considerable proportions of free phosphoric acid, which is very injurious to the crops. From his experiments he concludes that all methods for the determination of free phosphoric acid in superphosphate can only yield fallacious results, as the solutions examined never have the same composition as the original superphosphate.

That the therapeutic effects of many mineral springs is due largely to the fact that they contain radio-active substances dissolved in the water has been generally recognised for some time past, and accounts for the fact that the waters in question are efficacious only when taken on the spot, for if they are bottled and sent away, the radio-activity ceases before the water has been consumed. The paper by C. Engler and H. Sieveking in the issue of August 17 will be read with interest, as it gives the method used by them to determine the activity of a large number of German and Italian springs, and the results of their determinations. Some experiments with the very active sediment that is deposited by some of these springs are also of interest.

F. M. Berberich and A. Burr write upon the different methods for the estimation of fat in cream.

There is also a description of some small electric transformers for pressures up to 30,000 volts.

In *Chemische Industrie* for August will be found an account of the chemical industry of Japan, the data being taken from an official report by the German Consul at Kobe. Many interesting particulars are given concerning the production of camphor, menthol, peppermint oil, vegetable wax, agar agar, gall nuts, and other products.

Indian Notes.

MARKET movements (Calcutta, 1st August) are reported as under :—

Borax.—Stocks are very small, and dealers quote Rs.14.8 to Rs.15.8. per bazaar maund, weight, loose, prompt delivery. Supplies continue low and no arrivals from up country for weeks past.

Castor Oil Cake.—Export business continues nil, and prices are Rs.5.15½. for average and Rs.6.2½. for picked white, per bag of two maunds, f.o.b. for near and near forward shipments. Stocks and supplies are small.

Bone Meal.—Prices for all descriptions have kept fairly steady, and mills continue to quote Rs.72.0. to Rs.73.0. for New Zealand quality, Rs.68.0. for steamed quality, and Rs.61.8. to Rs.62.0. for unsteamed quality, guaranteed 4½% ammonia and 52% tribasic phosphate of lime, per ton of 20 cwts., f.o.b. for near and early deliveries.

Bone Dust.—Quotations are Rs.50.0. to Rs.52.0. per ton, f.o.b., guaranteed 3½% ammonia and 40% tribasic phosphate of lime, for near shipment. Offerings of this grade continue small.

Castor Oil.—Owing to pressure for delivery under old contracts, prices of ready oil have been forced up to Rs.19.0. for No. 1 fine pale, Rs.15.4½. for good seconds, and Rs.15.0. for thirds, in cases, per bazaar maund, weight, f.o.b., for prompt shipment. Offerings of all grades continue inadequate. For forward deliveries lower prices are accepted.

Cocoanut Oil.—Stocks and supplies continue small. Rates are Rs.22.6½. to Rs.22.8½. per bazaar maund, weight, f.o.b. in cases for near shipment.

Beeswax.—Business very limited. Quotations are Rs.80.0. to Rs.85.0. for locally refined sorts, Rs.70.0. to Rs.80.0. for raw per bazaar maund, weight, loose, prompt delivery.

Saltpetre.—Market quiet, with little business passing. Prices Rs.8.8. to Rs.9.8. for Furrackabad refined qualities, and Rs.8.3. to Rs.8.4. for ordinary 5% refraction quality, per factory maund, weight, loose, for near delivery. Offerings of lower refraction quality are small, while those of higher refraction qualities are bountiful.

Salt.—The market closed easy. Local stocks held, in maund weights were, ex Liverpool, 652,442 ; Hamburg, 213,341 ; Aden, 96,545 ; Saliff, 19,080 ; Phocee, 161,312 ; Spanish, 158,160 ; Port Said, 107,380 ; and Bombay, 13,658. Quotations per maund were :—Liverpool, Rs.49.0. to Rs.50.0. ; Hamburg, Rs.45.0. to Rs.48.0. ; Aden, Rs.45.0. to Rs.66.0. ; Saliff, Rs.47.0. to Rs.73.0. ; Phocee, Rs.68.0. ; Spanish, Rs.46.0. to Rs.73.0. ; Port Said, Rs.47.0. to Rs.71.0 ; and Bombay, Rs.47.0. to Rs.48.0.

Note.—The rupee can be taken at 1s. 4d., and the anna at a penny. The import duty on salt is Rs.1.0. per maund. The Indian maund is 82⅔ lbs., the factory maund is 74 lbs. 10 oz. 11 dwts., and the bazaar maund 82 lbs. 2 oz. 3 dwts. One cwt., *i.e.*, 112 lbs., equals 1 bazaar maund, 14 seer 8$\frac{8}{11}$ chittacks.

TENDERS FOR LUBRICATING OILS.—The Board of Trade have received from their correspondent in Johannesburg a copy of the conditions and specification relating to tenders for the supply to the Central South African Railways of the following quantities of lubricating oils, to be delivered as required, viz., 16,000 gallons of cylinder oil for locomotives, 28,500 gallons of heavy bearing axle oil, 20,000 gallons of castor oil, and 1,000 gallons of lard oil. Tenders, in sealed covers, marked outside "Tender for Lubricating Oils," must be received by the Secretary to the Tender Board, P.O. Box 4,570, Johannesburg, or delivered to him by hand at the Railway Offices, Johannesburg, by 11 a.m. on the 8th October next. The conditions and specification may be examined by British traders at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements in Reaction Towers, Regenerative Chambers, and the like. R. Scherfenberg, 28, Martin Lutherstrasse, Schöneberg-Berlin, Germany. British Patent, 4,366. Feb. 21, 1906. Date claimed under International Convention.

The inventor claims:—(1). Brick for making the inside structure of reaction towers, regenerative chambers and the like, of triangular, quadrangular or polygonal section, with corrugated or smooth surface, said brick having notches in the one bevelled half, fitting over the other bevelled half of adjacent bricks so as to allow of making a cross-bond.

(2.) Structure made of bricks for reaction-towers, regenerative chambers and the like, of triangular, quadrangular or polygonal section, said bricks having notches in the one bevelled half, fitting over the other bevelled half, the lowermost layer of the bricks being arranged in parallel rows, the distance between said rows being equal to the pitch of the notches, the following layer being placed in rows at right angles to the rows of the lower layer, so that each brick engages several bricks of the layer beneath it, a strong inside cross-bond being thereby produced, the bricks being thereby prevented from moving or giving way.

A Process for Extracting Copper from its Ores or Mineral Compounds. J. Gathy, 55, Boulevard de l'Hopital Mons Belgium British Patent, 18,574, 1906. Date claimed under International Convention, August 25, 1905

The inventor claims:—A process for the recovery of pure copper from its ores or compounds by chlorination and reduction of the resultant cuprous chloride by means of nascent hydrogen, characterised in that steam is introduced into a reducing furnace in which a mixture of the cuprous chloride, and charcoal or the like, have been brought to a dull red heat.

Improvements in Ammonia Recovery Gas Plants. W J Crossley, of Crossley Bros., Limited, Openshaw, Manchester, and T. Rigby, 23, The Square, Fairfield, Manchester. British Patent, 24,144. October 30, 1906

This invention has for its object improvements in producer gas plants designed with a view to recovering ammonia. In such a process, in order to obtain a large yield of ammonia, it is desirable to work the producers at a low temperature, and this is usually done by arranging for a large quantity of steam to be mixed with the air passing through the gas producer. A portion of the excess of steam passes through the producer undecomposed, and to make the process an economic success it is not only necessary to recover the ammonia, but it is essential that the great quantity of latent heat present in the water vapour should be recovered from the gas.

In most of the processes employed the ammonia is recovered at a temperature above that at which the water vapour is condensed, and before it is condensed, but in Patent No. 20,716, of 1901, a process is described in the specification which was calculated to simplify methods hitherto in use by condensing the water vapour and tars in the gas before the ammonia was absorbed, and this was done in a special way as described in the mentioned patent. By means of this improved process the plant was considerably simplified, and the process made easier to work. The object of the present invention is to still further simplfy the process, and instead of recovering the latent heat of the water vapour separately and the ammonia separately the operations are combined.

In the process referred to an apparatus was used mentioned in that specification as a washer. This washer was of improved construction, and was split up into compartments with the object of making zones of temperature, the water contained in the washer travelling constantly in the direction of the hottest end. This hot water was then pumped through an air-saturating tower, with the object of saturating the air supply to the producers with water vapour and cooling the water, the cool water flowing back to the coolest end of the washer and then recirculated. This apparatus was also arranged in such a manner that the ammonia was not lost, being passed onwards with the gases to an ammonia-absorbing tower. In the present invention sulphuric acid is added to the water circulating in the washer in such quantities that there is always present in the liquor a small quantity of free acid, and thus a fairly concentrated solution of sulphate of ammonia is obtained and circulated instead of water. The actual sulphate liquor thus becomes the medium for interchanging the heat of the gas and the water vapour condensed and also washes the gas; the small percentage of free acid present in the liquor absorbing the ammonia in the gas in a very efficient manner. It will be understood that the water vapour from the gas condensed by the liquor in the washer is added to this liquor and is more or less afterwards recovered in the air-saturating tower, portions of the liquor being taken off as required for further concentration by evaporation and crystallisation in the usual manner.

Improvements in Electric Transformer Furnaces. E. A. A. Grönwall, A. R. Lindblad and O. Stalhane, Ludvika, Sweden. British Patent, 7,791. April 3, 1907.

In electric smelting furnaces of the so-called transformer type, one of the greatest disadvantages has consisted in the great shifting of phases arising from magnetic leakage, which generally has been very considerable, while, in electric smelting

Digitized by Google

furnaces of the transformer type, on account of the high temperature, having regard to the magnetic leakage, the two electric circuits (that is, the primary coil and the smelting bath), cannot be placed as near each other as is desirable, it is necessary to resort to special measures in order to prevent the shifting of phases from being too great, which makes the use of expensive machinery necessary. The present invention has for its object improvements in transformer furnaces with a view to reduce these disadvantages.

The idea on which the invention is based is to place coils in the path of the leaking lines of force, to which coils suitable electric current is supplied, the coils being so arranged that the magnetic forces which are generated in the coils counteract the leaking lines of force. The specification, with two sheets of drawings, should be consulted.

SALT PRODUCTION IN MEXICO.

A UNITED States Consular report on the production of salt in the district of Manzanillo describes the primitive method of extracting the salt from the many shallow lagoons along the coast. At a convenient place, generally at high water mark, the following is constructed: On top of four strong posts, placed upright and protruding out of the ground about 6 feet, a flat covering is built on poles; on top of these about a 3-foot thickness of dry grass or straw is placed. When completed it is a flat-roofed shed with straw covering. This is to serve as the filter. Underneath this a receiving bowl is made of stone and lime mortar. At one side of the filter and bowl the evaporating pans are made of lime mortar, being shallow tanks not over six inches deep and divided into squares of about 150 superficial feet each. This completes the salt works. A layer of earth of one-fourth to one-half inch is then scraped daily from the exposed land that was covered with water when the lagoon was full in the wet season. This earth is carried in baskets on men's heads to the top of the filter and emptied on the straw roof. Water is then filtered through the earth and straw, and falls into the receiving bowl highly charged with salt. The liquid is passed to the evaporating pans, this being done with earthen jars. The sun evaporates the water and leaves the pure salt, which is piled up in the sun to dry. It is then packed in bags and conveyed by mules to the market.

The cost of making this salt is about $3.50. U.S. gold per ton, and it sells for at least twice that amount, even when the prices are lowest. It is considered the best obtained in the Republic, and commands the highest price. About 15,000 tons are now produced each year during the three months' season. With machinery much more could be made, and no doubt at much less cost. There is a ready market for many times the quantity now produced.

CONSUMERS OF SHELLAC have for some time past been feeling the inconvenience of high prices, says the *Manchester Guardian*. The two principal varieties, "button" and "orange" lac, are both used in large quantities by hat manufacturers in Denton, Stockport, Hyde, and other places round Manchester. Button lac is made in flat cakes, more or less circular in form, and, except to the expert, is a material whose exact value it is extremely difficult to gauge. Its appearance, its smell, the sound it makes when briskly broken, the feel of it, and even the taste of it, are considered carefully by the trained buyer. Orange lac is also used extensively in the manufacture of varnish. It is usually met with in thin, shivery flakes, and is much easier to judge than the other. It is only three or four years since the price of shellac was just one-third of what it is to-day; and no one appears to know the real cause of the advance. It has been attributed to the growing demand of the electrical trade and to the increasing use of high-grade varnishes, but it is doubtful whether either or both of these explanations is adequate. It is true that the demand increases rapidly every year, but it is equally true that the supply seems to increase *pro rata*. Probably the truth is that the standard of purity in the supplies is lower than formerly. India may ship larger quantities of shellac, but this season almost every quality has been inordinately adulterated with resin and other gums. It has been suggested also that the high prices have induced careless gathering, which will prove injurious to future crops. But official interest has been turned lately to the cultivation and harvesting of shellac with a view to maintaining the quality of the crops, and it is hoped that this may result in the maintenance or improvement of the standard.

THE MINERAL PRODUCTION OF SPAIN IN 1906.

THE Spanish Board of Agriculture, Industry and Commerce, in a report on the mineral production of the Kingdom, states that the output for 1906 reached a total of 498,450,851 pesetas, being an increase of 60,475,324 pesetas over the year 1905. This total is divided as follows:—

	Tons.	Value at the Mines. Pesetas.
Zinc	179,383	7,555,743
Copper	2,888,777	62,780,618
Iron	9,448,533	49,405,522
Iron (argentiferous)	120,415	507,393
Iron (pyrites)	189,243	800,302
Coal	3,095,043	37,236,436
Lead	105,095	18,422,409
Lead (argentiferous)	158,424	38,317,702

Answers to Correspondents.

We cannot undertake to reply to correspondents through the post. Those of our readers who have addressed queries to us should look in this column for a reply.

G. L. and Co., Ltd.—M.S. duly to hand.

W. O.—Reply to your query has been posted.

R. C. D.—Your letter has been answered by post.

C. L.—We are forwarding the information to our correspondent.

J. D. and Co.—We hope to deal with the subject in an early issue.

A. & B., LTD.—Thanks, but the matter has been dealt with previously.

CASEIN.—Will "Liverpool Inquirer" please communicate with us again, as his address has been mislaid, and we have some information to transmit to him.

Books Received.

"CONCRETE AND CONSTRUCTIONAL ENGINEERING": September, 1907.

"JAHRBUCH FUR DAS EISENHUTTENWESEN," (Ergänzung Zu "Stahl und Eisen.") Pp. 448. Dusseldorf: Kommissionsverlag von A. Bagel. 1907.

"CHEMICAL HANDICRAFT": AN ILLUSTRATED AND PRICED CATALOGUE OF CHEMICAL APPARATUS AND REAGENTS. Pp. 615. London: John J. Griffin and Sons, Ltd.

SEWAGE DISPOSAL.—Messrs. Archibald Constable and Co. will publish shortly a book on sewage disposal works by Mr. Hugh P. Raikes, A.M.I.C.E. The author is a well-known consulting engineer who has had considerable experience in the designing and construction of works. The volume will be a practical, up-to-date book dealing with the subject from the engineering point of view.

SULPHUR IN INDIA.—The sulphur mines of Sanni, Baluchistan, which have not been worked for many years, have recently been examined. Some of the clay bands are so full of sulphur that they burn with ease. The amount of sulphur impregnating the rock seems sufficient to give remunerative working.

PETROLEUM IN SERVIA.—The *Handels-Museum* of August 8 contains a copy of a notice inviting tenders for (1) the construction of a new reservoir in Belgrade to contain 2,500,000 kilogs. of refined petroleum at a summer temperature of 45° C.; (2) the alteration of the old reservoir from 2,500,000 kilogs. to 2,000,000 kilogs. containing capacity; (3) embanking the site and macadamising the area in connection with the above. A deposit of 20% of the amount of the tender must be paid into the Kassa der Monopolverwaltung before 14th October. Tenders for any or all of the above contracts may be sent in to the Monopolverwaltung, Belgrade, until 15th October. The length of time in which the work can be carried out must be stated in the tenders, which must be stamped with a ten dinars stamp.

RUSSIAN MINERAL FERTILISER DIFFICULTIES.—The *Xosiastvo* publishes a long article on the dearness of mineral fertilisers in Russia, which is mainly caused by the immense distances between the sources of supply and the points of consumption. In Russia there is only one factory producing Thomas slag; this is near the town of Taganrog, and the carriage of the fertiliser to where it is most in demand—the Baltic provinces and Poland—is so expensive that the farmers of the areas named prefer to get their supplies from abroad. The whole quantity of Thomas slag produced, amounting to 700,000 poods (13,000 tons) a year, is used up in sixteen governments. A somewhat similar state of affairs exists as to superphosphates, to produce which there are several factories, but they are all concentrated in Western Russia, and whilst such a state of the producing industry continues the writer of the article urges a great reduction in railway carriage.

NEW YORK PRICES CURRENT.

SERIOUS DOCK FIRE AT ANTWERP.—Much damage has been done during the past week by fire at the Antwerp Docks. It is suspected that the fire is the result of incendiarism. The damage is estimated at 4,000,000 francs.

BY-PRODUCTS AND THEIR UTILISATION.—The question of by-products and their utilisation (says *Cassier's Magazine*) is one which has been discussed many times and from various viewpoints. There is no doubt that too much effort may be made to save the last fragment of material or power, and that the cost may be out of proportion to the saving. There are examples, however, and these are multiplying, in which modern technical developments are showing that what was formerly considered a by-product may hereafter turn out to be the principal source of revenue, while the original product of a process is relegated to the second place. There is no doubt that in the modern power plant extensive and costly methods are employed for the sake of getting the maximum amount of power from the steam, these including feed-water heaters, superheaters, condensers, multiple-expansion engines, etc., and these are all fully justified if mere economy of steam is the ultimate end in view. The real aim of all mechanical improvement in such a plant is the economy of money, and any other saving must be regarded as a means toward that end, and it is quite possible to save steam at the expense o increased charges for wear and tear, depreciation, and interest on first costs. If, under these conditions, it is found that the absorption system, using large quantities of steam, be found desirable from a commercial point of view, it is not impossible that the refrigerating plant may have power to sell as a by-product, or rather that both power and cold may become joint products of a modern central station. Such a station would be distinguished by the simplicity of its power generating machinery, and possibly also distinguished by the satisfactory returns which it would make to its shareholders.

Anglo-Mexican Oilfields.—Mr. J. B. Bergheim, presiding at a statutory meeting on Thursday last, said that all the machinery had been ordered since they were constituted two months ago, and had arrived at the ports. When they would start drilling he could not say definitely; he thought drilling would have commenced by December 1. Nothing had transpired since they took over the property to weaken their faith in it. As an oil venture it started with everything in its favour.

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, August 20, 1907.

(Rate of Exchange, $4.38 = £1.)

Nitrate of soda remains in an unchanged condition, and spot parcels are being offered at $2.45. per 100 lbs. Sulphate of ammonia remains dull, at $3.05. to $3.07½. for future, while prices for spot are being shaded a little to stimulate business. Grey muriate of ammonia for galvanising is quoted at 5¼c. to 6¼c. per lb., and is selling principally on contract; white electrical is dull, and can be bought as low as 5¼c. per lb. Lump sal ammoniac is well maintained at 9¼c. per lb. Lump carbonate of ammonia is moving very slowly at 7⅞c. to 7⅞c. Bleaching powders are quoted at $1.30. per 100 lbs., and are rather dull. Alkali and caustic soda are unchanged. Sulphate of copper is weak, and we expect reduction in prices in the near future. White powdered arsenic is dull, but prices are well maintained, and even a shade higher for future. Red Saxony arsenic is moving along slowly, and prices are about the same. Calcined potash, 80-85%, is in fairly good demand, and prices are maintained at 3⅞c. to 3¾c. per lb., with the hydrated at 4¼c. per lb. Caustic potash, 75%, is in a little better demand, but prices remain about the same. Chlorate of potash and soda remain unchanged. Bichromate of potash is in good demand at 8½c. to 8¾c. per lb., and soda at 7¼c. to 7½c. per lb. Oxalic acid is in good demand, although the price has broken a little. It is now quoted at 8⅜c. per lb. for spot.

TAR AND AMMONIA PRODUCTS.

Thursday.

Benzols: Values are given at 8¾d. for 90's, and 8½d. to 9d. for 50-90's. Crude tar, 15s. 6d. to 20s. per ton, Thames; 1½d. to 1⅝d. per gallon, delivered. Refined tar, 12s. per barrel. Gas Company, 12s. 6d. Pitch, 26s. 6d. to 27s., f.o.b.; Gas Company, 29s., forward; East Coast, 25s. to 25s. 6d.; forward, 20s. to 20s. 6d.; West Coast, 24s. to 24s. 6d.; forward, 2s. more. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 10½d. to 11d.; pure, 1s. 3d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5¾d.; 60%, 1s. 8d.; 75%, 1s. 11¾d. to 2s. Crystals, 39-40, 5¾d.; 34-35, 5½d. Cresylic, 95%, 1s. 1d. to 1s. 1½d. Anthracene, 40 to 45 per cent. A, 1½d. to 1¾d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia quiet. Nearest values are:—Beckton, £12. 1s. 3d.; Beckton terms, £11. 11s. 3d. to £11. 12s. 6d.; next year, £12. 2s. 6d. London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; and Leith, £12.; forward, £12. 5s.

Nitrate of soda, ordinary, 11s. 3d.; and refined, 11s. 9d. Liverpool, ordinary, 11s.; refined, 11s. 1½d. Official quotations:—Cargoes off coast or due, 11s. 1¼d.; ditto for prompt shipment, 11s. 6¼d.

FERTILISER MATERIALS.

Friday.

There is a complete absence of activity, but prices for all descriptions of manure material remain steady.

There is no change to report in mineral phosphates, raisers of all grades still maintaining a firm attitude, and being busy with the execution of contracts.

East Indian bone meal attracts but little attention, shippers requiring £4. 17s. 6d. per ton, nett, c.i.f. terms Liverpool, for 4½ and 52% quality. On spot, £5. 5s. to £5. 10s. per ton, according to quality, ex store, is asked.

Nitrate of soda remains a very quiet market, but quotations are steady, at 11s. 1½d. to 11s. 4½d. per cwt., for ordinary and refined qualities, respectively, ex store.

THE LONDON METAL MARKETS.

Thursday.

Copper: Standard brands, £74. to £74. 5s. cash, and £73. 17s. 6d. to £74. 2s. 6d. three months. Tin: G.M. quality, £168. 5s. to £168. 15s. cash, and £168. to £168. 10s. three months; English, £170. Lead: soft foreign, £19. 15s. for September; £19.15s. for November-December; and £21. 5s. for December shipment, ex ship; hard, £18., f.o.b. Antimony, £35. to £38.; Chinese crude, £25., c.i.f.; ore, £10. Bismuth, 6s. 6d. Quicksilver, £7.; seconds, £6. 10s. Nickel, £175. to £185. Aluminium, £155. to £160. Wolfram, 48s. to 49s. Pig iron closing prices:—Cleveland, 55s. 5d. cash, and 55s. 5d. one month.

MISCELLANEOUS CHEMICAL MARKET.

Friday.

Business has been fairly good during the past week, and values, as a whole, are well maintained. Bleaching powder is still quoted for 1908 delivery at £4., softwoods, on rails, and the majority of the large contracts have now been settled. The price of caustic soda for next year is not yet fixed. Prompt quotations are unchanged, viz.: 74%, £10. 5s.; 70%, £9. 15s.; 60%, £8. 15s., f.o.b. Liverpool. Ammonia alkali, 58%, firm at £4. 10s. on rails, for odd orders, and 5s. per ton less for contracts. Chlorates and bichromates are without alteration. Inquiry for sulphate of copper is rather quiet, and price easy for spot and early shipment, at £26., f.o.b. Liverpool. Recovered rock sulphur, £4. 10s., rails. Saltcake firm, at 40s., f.o.r. American brown acetate of lime dull, at £8. 7s. 6d., c.i.f.; grey, £12. 10s. Acetic acid and other acetates are unaltered. Potash, caustic and carbonate, is again exceedingly scarce on the spot, and higher prices are being obtained. Prussiates of potash and soda are again weaker. Oxalic acid steady, at 3⅞d. to 3¾d. per lb., ex store. Nitrate of soda, 11s. 3d., f.o.r. Garston. For white powdered arsenic there is more inquiry, and quotations rule fairly firm at £31. to £31. 5s., Garston, for best brands. Borax has been advanced to £16. for crystals, and £17. per ton for ground.

LIVERPOOL DRYSALTERIES.

Thursday.

Montreal potashes quiet, at 35s. 6d. to 36s. per cwt. Pearl ash nominal. Cutch steady. Gum arabic quiet. Gum copal: A parcel of Brazilian is reported to have been sold at 52s. per cwt. from store. Logwood and fustic quiet. Castor oil quiet, at 3½d., for good seconds Calcutta; 3 11/16d. for first pressure French; 3¼d. for second pressure French, all on spot; and 3 9/32d. for Calcutta shipment on to January. Gambier: Block 18s. 7½d. to 19s. on spot; and 18s. for June-July and July-August shipment. Cubes, 28s. 6d. to 29s. on spot; and 27s. 10¾d. for August-September, and September-October shipment. Shellac quiet, at 185s. for fair T.N. orange on spot. American powdered starch, 10s. 3d., on spot, and 9s. 9d., c.i.f., for shipment; pearl, 9s. 9d., on spot, and 9s. 3d., c.i.f., for shipment. Glucose: American liquid, 43%, 11s. 3d., on spot, and 9s., c.i.f., for shipment. Cream of tartar, 98%, foreign powder, 81s.; 95%, 79s. Tartaric acid, English, 11¼d. on spot; foreign, 11d. Citric acid: English, 1s. 10½d. on spot; foreign, 1s. 10¼d.

LIVERPOOL OIL AND COLOUR MARKET.

Thursday.

OILS.—Palm oil quiet, sales including Lagos at £29. 10s. per ton. Cottonseed oil steady at 30s. 9d. to 31s. 3d. for Liverpool refined in export barrels. Linseed oil firm at 24s. 9d. to 25s. for Liverpool makes in export casks. Tallow steady, at 33s. per cwt. for South American beef. Rosin steadily held at recent currencies. Turpentine quiet, at 41s. 3d. on spot. Petroleum steady, at 6½d. for Russian and Roumanian, and 7d. to 8d. for American refined oils. Petroleum spirit in fair demand, at 1s. 0¾d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 16s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder, 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

Digitized by Google

TYNE CHEMICAL REPORT.

THURSDAY.

Market remains steady, but without any change in prices. Shipments continue fairly good. Soda crystals, locally, are firm, at £3. to £3. 2s. 6d. per ton, gross weights. Caustic soda steady, at £9. 15s. for 70%, and £10. 10s. per ton for 76-77% Bleaching powder quiet, at £5. per ton. Sulphur scarce and firm, at £5. to £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77%, £10. 10s. per ton, nett; do., 70%, £9. 15s. per ton, nett; recovered sulphur, 2 cwt. bags, £5. 5s. per ton, nett; alkali, 30%, £4. 17s. 6d. per ton, nett; do., 36%, £5. 2s. 6d. per ton, nett; do., 40%, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5/7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (saltcake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid, 60-62%, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 50-60%, £13. per ton, nett; do., crystals, 45-48%, £12. per ton, nett; strontium hydrate crystals, 90-95%, £8. 10s. per ton, nett; do., carbonate, 90-95%, £10. 15s. per ton, nett.

COALS.—Market generally firm, with a brisk inquiry for all classes, and many of the principal collieries are fully sold for September. Market for forward business is somewhat unsettled owing to a possibility of labour troubles in Northumberland. To-day's prices:—Best Northumbrian steam, 16s. 6d. to 16s. 9d. per ton; second qualities, 16s. to 16s. 3d. per ton; Northumberland smalls, 10s. to 10s. 6d. per ton; best gas coals, 15s. 6d. to 16s. per ton; Durham bunkers, 14s. 3d. to 15s. per ton; coking coals, 14s. 3d. to 14s. 6d. per ton; household coals, 16s. to 17s. 6d. per ton; foundry coke, 25s. per ton; gas coke, 20s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

The position in sulphate of ammonia is not materially changed since last report. For spot, f.o.b. Leith, £12. 2s. 6d. was paid, but this was a special parcel, and quite small. The real spot value is about a good £12. Nothing is doing in forward, makers still being disposed to stand off for a time. Sulphate of copper continues weak, but there has not been any further marked fall. The general chemicals continue healthy in tone, at prices showing little or no change. Forward business seems a shade easier. Firmness still marks the purely local section of mineral oils and paraffins. Makers are now almost fully contracted forward in burning oils, and sales to English customers, which formerly had a slight preference, are now rated the same as those to Scotch buyers. Creosote gets stronger, and the figure to-day, naked, f.a.s. Glasgow, is 2¼d. to 2½d. per gallon.

Chief prices current are:—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½% for Scotch and English deliveries (for export, 3¼d. nett, f.o.b. Glasgow); bichromate of soda (home-make), 3d., less 2½% for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16., and boracic acid, £25., nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream, 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace), 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 1½d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 2¾d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3¼d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¾d.; ordinary sorts, 6½d. and 6¼d. (new season's contract prices), at Glasgow and other big centres; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42. and £40., less 2½% any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s., nett, Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 5s. 3d., prompt f.o.b. Leith; sulphate of copper, £26. 15s., less 5% Liverpool, prompt.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—Refined cotton oil, after advancing to 28s. 6d., fell away again, but closes steady. Linseed oil has risen by about 2s. to 3s., and closes firm at the advance. Turpentine is easier. Amongst the principal imports here to date are:—Wheat 2,753,740 qrs., against 2,661,921 qrs.; flour 147,657 cwts., against 253,668 cwts.; linseed 524,417 qrs., against 356,412 qrs.; rapeseed 61,700 qrs., against 66,018 qrs.; cottonseed, Egyptian, 127,908 tons, against 111,443 tons; other kinds, 125,172 tons, against 100,978 tons; oilcake 18,136 tons, against 28,830 tons; hemp 92,647 cwts., against 116,153 cwts.; olive oil 3,490 tuns against 2,941 tuns; tar 4,373 brls., against 7,318 brls. Amongst the weekly imports are:—Lard, 5,279 cwts.; margarine, 2,137 cwts.; sugar, 21,110 cwts.; glucose, 40 cwts.; wool, 53,248 lbs.; hemp, 578 cwts.; hides, 170 cwts.; colours, 1,608 packages. Exports:—Oil, 9,314 cwts.; colours, 2,149 packages; chemicals, 2,006 packages. Refined cotton closes steady at 28s., spot naked; September-October, 26s. 3d.; November-April, 23s. 4½d.; casks £1, and barrels 27s. 6d. per ton extra. Exports during the week:—1 ton Denmark, 59 Germany, 16 Holland, 1 Sweden; total, 77 tons. Cottonseed quiet, at £8. 5s., store; £8. 3s. 9d. passage; September, £8.; October, £7. 7s. 6d.; November-January, £7. 13s.; Bombay, September-October, £5. 16s., buyers. Linseed oil maintains a strong position, closing firm at 22s. 3d. paid; September-December, 22s.; sellers, January-April, 21s.; boiled and refined, £1. to £1. 10s. per ton extra. Exports during the week:—3 tons Belgium, 7 France, 4 Norway, 1 Turkey; total, 15 tons. Linseed: Good business done at an advance of 6d. Market closing firm. La Plata, 42s. 3d. spot; September-October, 43s., paid. Turpentine, 41s.; September-October 41s. 6d.; January-April, 43s.; Russian ditto, 20s. 6d. Rosins unchanged. Olive oil, Levant, £42. per tun.

CAKES.—Linseed cakes are 2s. 6d. per ton dearer on the week, with fair demand and firm market. Cotton cakes dearer and scarce. Bombay ditto well held for full prices.

New Companies.

Cullis, Phillips and Co., (1907), Ltd.—Capital £1,000., in £1. shares (400 preference). This company has been formed to acquire the undertaking and all or any of the assets and liabilities of Cullis, Phillips and Co., Ltd., incorporated in 1897, to adopt an agreement with H. Charlesworth, the liquidators of the said company, and to carry on the business of manufacturers of and dealers in bricks, tiles, pipes, cement, stone, tar, pitch, asphalte, terra-cotta, plaster of Paris, whiting, artificial stone, etc. No initial public issue. The first directors are T. Cullis, A. Phillips and H. Marks, each of whom may retain office while holding 50 shares. Registered office, 31, York-place, Portman-square, W.

New Brunswick Canadian Salt Co., Ltd.—Capital £50,000., in £1. shares. This company has been formed to carry on the business of salt and chemical manufacturers, etc. No initial public issue. The first directors are to be appointed by the subscribers; qualification £250.; remuneration £150. each per annum, and 2½% of the profits available for distribution after paying 10% on the ordinary shares, divided. Registered office, Dixon House, Lloyd's-avenue, E.C.

Rubber Concessions, Ltd—Capital £5,000., in £1. shares. This company has been formed to acquire an option for the purchase of a concession for the collection of rubber and other purposes in Republic of Ecuador, granted at Risamba by the Government of Ecuador to Francisco I. Salazar in September, 1903, and with a view thereto to adopt an agreement with C. A. V. Conybeare and G. Gall. No initial public issue. Registered without articles of association. Registered office, 46, Leadenhall-street, E.C.

Sambas Rubber and Gutta Percha Co., Ltd.—Capital £160,000., in £1. shares. This company has been formed to acquire certain concessions and property in Sambas, Dutch West Borneo, now owned by the Cultuur and Handelmaatschappij Siloewas, of Amsterdam, and with a view thereto to enter into an agreement with the Netherlands Indies Syndicate Ltd. Minimum cash subscription £38,000. The first directors are to be appointed by the subscribers; qualification £250.; remuneration (except managing director) £100. each per annum and £50. extra for the chairman. Registered office, 3-4, Fenchurch-street, E.C.

LATE ADVERTISEMENTS.

EXPERIENCED Tar Distiller and Sulphate of Ammonia maker requires Situation; charge of small works preferred; best of references given.—"1,483," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

WANTED, thoroughly experienced Manager or Foreman for Wood Charcoal Chemical Works; state full particulars and salary expected, in confidence.—"1,495," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

FRENCH Analytical Chemist (Diploma) desires Position in Laboratory or Manufactory; highest references.—Address, "Chemical," Birchall's Advertising Offices, Liverpool.

ANALYTICAL Chemist, Dutch, with good experience, desires Appointment as Assistant in laboratory or works.—"1,496," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

BASIC SLAG.—Wanted, Agency for Ireland for Sale of above.—Address, "Slag," Messrs. Deacon's, Leadenhall Street, London

SECOND-HAND BOOKS at Half Prices! New Books at 25 per cent. Discount! Books for Chemical, Pharmaceutical, and for all Trades and Examinations supplied; sent on approval. State wants. Send for List. BOOKS BOUGHT.—C. N. FOYLE, 135, Charing Cross Road, London, W.C.

YOUNG Man, with some experience in Chemical and general engineering, desires Post as Draughtsman to works engineer, or in drawing office of chemical engineers.—"1,494," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates :—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order :—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

CURRENT TOPICS.

THE AUGUST TRADE RETURNS.

THE Trade and Navigation Returns for August show continued increases in both imports and exports.

The figures for the month are :—Total imports (value c.i.f.) £49,296,585., against £48,889,137., an increase of £407,448. Total exports of British and Irish produce (value f.o.b.), £37,355,044., against £33,492,614., an increase of £3,862,430. The comparison with 1905 shows an increase of £2,439,856. in imports, and an increase of £7,837,208. in exports.

The imports of chemicals, drugs, dyes, and colours in August amounted to £951,363., against £856,982. in 1906, an increase of £94,381. The imports of bleaching materials were valued at £3,581., against £6,227., and of soda compounds £9,932., against £8,149. in 1906.

The exports of chemicals, drugs, dyes, and colours in August amounted to £1,319,825., against £1,147,120. in 1906, an increase of £172,705. During the month the principal items were :—Bleaching materials, 69,497 cwts., valued at £14,996., against 73,686 cwts. and £15,932. in 1906. Coal products (not dyes), value £66,860., against £75,606. in 1906. Copper sulphate, 717 tons, valued at £21,577., against 617 tons and £14,747. in 1906. Dyestuffs, £31,282., against £24,810. in 1906. Glycerine, £34,939., against £18,814. in 1906. Chemical manure, 76,445 tons, valued at £388,064., against 78,359 tons and £328,922. Muriate of ammonia, 11,227 cwts., valued at £14,242., against 12,588 cwts. and £16,766. in 1906. Painters' colours and materials, 168,892 cwts., valued at £211,938., against 152,699 cwts. and £184,730. in 1906. Soda compounds, 462,913 cwts., valued at £157,433., against 420,017 cwts. and £125,147. in 1906. The exports of salt in August amounted to 55,107 tons, valued at £44,252., against 61,673 tons and £43,472. in 1906. Exports of "unenumerated chemicals" were valued at £224,172., compared with £217,907. in 1906.

The imports of oil seeds, nuts, oils, fats, and gums in August amounted in value to £2,952,022., against £2,243,061. in 1906, an increase of £708,961. The figures for petroleum were 22,720,548 gallons, valued at £461,293., against 29,382,876 gallons and £564,345. in 1906. The value of exports of oil seeds, nuts, oils, fats, and gums was £283,649., against £230,097., an increase of £53,552.

The imports of metals and minerals during August were :—Copper ore, 8,803 tons, valued at £110,854., against 9,039 tons and £113,485. in 1906. Copper (regulus and precipitate) 6,965 tons, valued at £289,245., against 7,476 tons and £336,344. in 1906. Lead (pig and sheet), 17,866 tons, valued at £352,212., against 16,789 tons and £275,000. in 1906. Pyrites of iron and copper, 61,930 tons, valued at £94,207., against 54,572 tons and £95,270. in 1906. Quick-

Digitized by Google

silver, 56,250 lbs., valued at £4,925., against 37,500 lbs., valued at £3,500. in 1906. Silver ore, value £225,253., against £175,588. in 1906. Tin, 4,345 tons, valued at £753,283., against 3,529 tons and £630,196. Zinc (crude), 6,490 tons, valued at £146,731, against 7,523 tons and £189,175.

THE INDUSTRIAL DEVELOPMENT OF JAPAN.

The last report of the British Consul-General in Japan contains some interesting notes on the industrial development of the country. The capitalised wealth of Japan is approximately £2,311,000,000., excluding Formosa. It is evident that there is room for a large expansion of Japan's aggregate wealth, even if she never approaches the considerable per capita wealth of other countries; when her natural resources are taken into consideration, it is probable that this development and appreciation of values will take place. Between 1895 and 1904 the production of gold had increased over 200%, copper nearly 50%, iron nearly 50%, iron pyrites 300%, coal nearly 125%, sulphur over 50%, and petroleum over 600%.

Japan has large forest areas which are a source of potential wealth, while her progress in cotton spinning, sugar refining, match manufacture, etc., shows considerable possibilities in the way of industrial expansion. The difficulties of over-rapid development, the growth of luxuries, and the increased cost of living will, with other obstacles, have to be met; but the net result will be a steady expansion all round. Japan's chief aim is the development of her resources and trade, and it is for this reason that the introduction of foreign capital in the shape of loans or investments is desired by her. Development cannot come without capital, and Japan seeks to develop in every direction.

Railways, harbours and industries at home, railways and mines in Corea and Manchuria, shipping, and trade are all receiving attention and demand money, making the question of capital one of vital importance for the country. The matter is one of interest to British trade, because the main avenue of commercial expansion for Japan is in the direction of China and Corea. Her high tariff will, whenever necessary, secure to Japan much of the control of her own markets, and will place her in a favourable position to secure the major share of increased trade in those countries. Her geographical proximity, natural concentration of attention on Far Eastern trade, numerous subjects resident in Far Eastern ports, Government encouragement, and, perhaps, in time, control of capital, will all contribute to give her traders very considerable advantages, and render specially necessary the conservation of such advantages of position, knowledge and reputation as British traders already possess. It is this probable future expansion of Japan in Far Eastern markets which renders such matters as trade-marks of prime importance. Even in the case of merchants interested only in China and Corea, registration of trade-marks in Japan may often serve a useful purpose. Priority of registration may, in any case, prove advantageous; while, whatever the solution of the trade-mark question in China may be, Japanese offenders will, in many instances, be more easily pursued in their own country. The difficulties arising from a Japanese having legally registered in Japan a trade-mark registered by a British merchant in the United Kingdom, and using the trade-mark simultaneously with his British competitor in China, would then be avoided.

Virginia-Carolina Chemical Co.—Messrs. Hales and Sons notify that a quarterly dividend of $2. per share (at the rate of 8% per annum) has been declared upon the preference stock.

IMPORTS OF CHEMICALS, DRUGS, DYES, AND COLOURS.

THE following returns, which are taken from the foreign and colonial statistics of the United Kingdom, give the amount and value of chemicals, drugs, dyes, colours, etc., imported during August, 1907, as compared with August, 1906:—

CITRIC ACID PRODUCTION.

IN a letter to Sir Daniel Morris, the Imperial Commissioner of Agriculture for the West Indies, Mr. Jones, the Curator of the Botanical Station at Dominica, raises the interesting question whether the world's supply of citric acid is all produced within areas dominated by active volcanoes, as Sicily, parts of Italy, Montserrat, and Dominica. "Is this," he asks, "merely a coincidence, or is it the result of long experience proving that such localities are best suited for the growth of lime and lemon trees?" The British Consul-General in Italy, in his annual report just issued, observes that with respect to his Consular district, or at all events to such parts of it as grow oranges and lemons, citrons, and bergamotte, in profusion, it must be said that they are all dominated by active volcanoes, Vesuvius and its region, Etna, Stromboli and Vulcano, commanding as it were the entire citric zone. "It is, of course, obvious that the volcano must be situated in a latitude in which these delicate plants can thrive. We cannot expect lemons to grow on Hecla merely because it is a volcano, although no doubt the soil contains the elements of potash and phosphoric anhydride which form the soil best adapted to any fruit tree, and therefore to any sort of lemon tree. It is a fact that the groves of Sorrento, Nocera, and Mandanice prosper the better in the proportion that they find land richer in lapilli, which, as is known, are formed of hardened fragments of volcanic pumice stone. These facts are not sufficient to prove the case altogether, for many lemon groves near Messina and in Calabria, though dominated by Etna, Stromboli and Vulcano, are found on lands of granitic formation; and others in the same region and other regions of Sicily are in alluvial deposits with chalk or clay chalk of tertiary formation."

NITRATE STATISTICS.—The Permanent Nitrate Committee, in their Public Statistical Circular for September, state the shipments of nitrate of soda as follows:—(1) Total exports to Europe, August, 1,874,400 quintals. (2) Imports, Europe, August, 62,230 tons. (3) Deliveries, Europe, August, 43,000 tons. (4) Visible supply, Europe, 1st September:—Stocks and afloat, 385,390 tons.

WAGES IN WIDNES.—The *Liverpool Daily Post* says:—"The members of the engineering societies in Widnes have recently asked for an advance of 2s., and this has been granted by the Widnes Alkali Company, the Castner-Kellner Co., the Manchester Ship Canal Company, and several other firms. Still there are two big local firms who have not acceded to the men's request, and if the employers do not grant the demands the men will go out on strike. Influence is being brought to bear upon the employers, and it is likely that the advance will be made."

THE ITALIAN OLIVE OIL INDUSTRY.

THE British Consul-General at Naples in reporting on the olive crop in South Italy in 1906 states that the export during the past year, compared with preceding years, has been short. The supply has almost exclusively been absorbed by the United Kingdom and home consumption; an insignificant quantity has been forwarded to Russia, where our oils compete with those of the Ionian Islands. Demand from North Italy has been very active, owing to the excellent quality of the 1905-06 crop, which, on account of its very low acidity and almost absolute lack of smell, was accepted as edible oil and used, especially by the rural population.

During recent years positive progress has taken place in gathering and grinding the olives, and also in the system of preserving freshly-ground oil. As a consequence of these improvements the disposable stocks of common oils are yearly diminishing, whilst, on the other hand, the quantities of edible, half fine and fine oils are increasing. This ensures a very satisfactory continuity between the grower and the consumer, especially in places where only fine oils command a market.

The stock on hand in Gallipoli on December 31, 1906, consisted of excellent oils remaining from 1905, but there are also burning oils for Russian use and some lots of inferior qualities of strong acidity. As preceding reports warned importers, the result of the crop of 1906 was very poor.

The year 1906, which recorded a sensible rise in the prices of all articles of world trade, brought an advance in price for oils. This rise was occasioned neither by speculation nor by increased consumption, but was to be attributed to the general deficiency of production. Spain, which in some favourable years has such an enormous production as would by itself be sufficient to supply a great part of the world, had hardly sufficient to satisfy the wants of home consumption; its prices were always sustained and still are about £10. per tun higher than the Italian, and export to foreign places is therefore paralysed. Neither the Levant, Tunis nor Morocco with their moderate crops were able to make good this scarcity. The Ionian Islands competed with success on the foreign markets, where they sold their produce at remunerative prices, but now their stocks must be much reduced, if not quite exhausted.

Prices on January 1, 1906, for prompt Gallipoli stood at £34. per tun, f.o.b.; they reached during the first six months £38., and declined at the beginning of July to £35., but afterwards they advanced again up to £41. A slight reaction is shown by present quotations, owing to the position of the exchange, whilst high premiums are paid for special qualities. In conclusion, till December there is no way for consumers but to apply for the small stock still on hand in some parts of South Italy. The choice qualities of these oils will very soon be exhausted, so that purchasers should cover their wants at once, or they will incur risk of disappointment.

The following table shows the export of olive oil (in Imperial tuns) from Gallipoli during the year 1906, as compared with preceding years:—

Mr. Vice-Consul Berner (Bari) reports that the yield of olive oil in his district was a poor one, respecting both quantity and quality, the keiroun (oil-worm) having caused great havoc, especially in the plains along the coast. Fortunately large stocks of well-preserved old oil, of superior quality, were existing to meet exacting demands. These stocks, however, being now greatly reduced, it is feared that they will hardly suffice to fulfil requirements until next autumn. Owing to the chilly weather in the first quarter of the year, trees are very much behind in their development, and no forecast can be made as yet in regard to the prospects of the next crop. Under the patronage, and with the subvention of, the Government, studies are being carried on to find means to prevent the spreading of the oil-fly, which, ever since the Roman era, has appeared almost every year, injuring the olives more or less, and often completely destroying them. Some appreciable results have been obtained with the dachicida (larva-killer) invented by Mr. De Cillis, a mixture of 65% molasses, 31% honey, 2% glycerine, and 2% arseniate of soda, of which composition a solution of one part with nine parts of water is used for syringing trees with common hand-pumps (in the same way as vines are treated with sulphate of copper against cryptogamic diseases) periodically—say, from four to six times—the first syringing to take place as soon as the young fruit comes out. In groves where such experiments have been made, only from 10 to 20% of the olives were attacked by the insect; whilst up to 80% were damaged in others adjoining them, where such treatment had not been adopted. As a matter of fact, however, the system proposed does not solve the question, but is a palliative only; for, apart from the cost of the stuff, and heavy expenses for wages, there remains the difficulty of inducing all the farmers, without exception, to follow suit, and the impossibility of applying it to districts where trees, as in Calabria and Basilicata, attain an enormous height (up to 60 feet), which cannot be reached by hand-pumps. It is obvious that, if even a few centres of infection only remain, the oil-worm, when in the stage of fly, will easily spread thence to other quarters. To radically extirpate it, according to the advice of competent persons, the simplest way would be to bring it to starvation by gathering all the fruit by the end of March (a Bill in Parliament would have to pass for that purpose), for it is an acknowledged fact that the invasion of the keiroun only takes alarming proportions in years following a plentiful crop. Then, on account of the abundance, harvesting is belated in many districts, the olives remaining on the trees up to May, and even June, when in other districts the new fruit is already coming out. The oil-fly (mild weather at that period of the year favouring its multiplication), from the old fruit gets on to the new for subsistence, but would certainly perish for want of food if the olives were gathered before April, when trees only begin to blossom.

Cottonseed Oil in Austria-Hungary.—The Acting British Consul at Trieste reports that, according to a recent official publication, the price of cottonseed oil at Trieste has increased by 40%. The new Customs Tariff of 1906, which brought the duty on cotton oil from 8 kronen (6s. 8d.) to 40 kronen (£1. 13s. 4d.), has greatly curtailed the importation of this article. During the first six months of 1906, 72,056 barrels, with 12,970 tons, were imported into Trieste. Of this quantity, 63,296 barrels came from America. During the same period of 1907 only 3,909 barrels with 704 tons were imported into Trieste (2,262 barrels from America, 876 barrels from England, and 771 barrels from other places). On 30th June, 1907, there was a stock of only 426 tons in that port.

The Sir John Cass Technical Institute.—The new session of the Sir John Cass Technical Institute will open on Monday, September 23rd. The work of the several departments has been considerably reorganised since last year. Apart from systematic courses in physics, mathematics, and chemistry, in which provision is made for students preparing for degrees of London University in Experimental Science, special courses of instruction will be given in physical chemistry, brewing and malting, and in several branches of advanced physics, including radio-activity. The courses in physical chemistry will include general physical chemistry, electro-chemistry, and a laboratory course of practical work. The instruction in brewing and malting will also include laboratory work of a technical character, in addition to a course of lectures designed for those engaged in the brewing and malting industries, in which full attention will be given to modern methods of work. The teaching in metallurgy, which for the past four years has formed a distinctive part of the work of the Institute, has now been established as a separate department, and a full graded curriculum, extending over three years, is provided, which includes advanced instruction in the metallurgy and metallography of the most important metals, and the analysis of fuel and of gas for technical purposes, in addition to systematic courses of lectures and laboratory work in general metallurgy.

THE BELGIAN CEMENT TRADE.

CONSUL-GENERAL HERTSLET, in his report on Belgian trade and commerce for the year 1906 and the first half of 1907, observes that there is little to be said in regard to the cement industry, except with reference to the statistics of output and exports and particulars of the present prospects of the trade in addition to what has been mentioned in previous reports. He continues :—"Were it not that I should be guilty of repetition, attention might again be called to the systematic habits of the dealers in Belgian cement in passing off their productions of inferior quality as an article of British manufacture or British origin at exceptionally low prices, which cannot be approached by makers in the United Kingdom so long as they retain the high standard for which British cement has been, and still is, famous. It is manifestly unfair to the maker in the United Kingdom that Belgian cement can be sent to the British Isles, the colonies and foreign countries in the enormous quantities which it is, bearing descriptions and labels in English, the obvious intention of which is to encourage the supposition that the article sold is British made. The blame cannot be put so much upon the manufacturers themselves as upon the commission agents and dealers of that class, who furnish any labels that may be required to the makers to attach to the barrels or casks when forwarded from the works, many of which labels are without doubt infringements of trade-marks of makers in the United Kingdom. Persons who purchase Belgian cement are also open to criticism, provided that they dispose of it to credulous buyers with British labels attached. Many Belgian commission agents are aware of the risks they run in shipping cheap Belgian cement bearing labels which are registered trade-marks of British firms. With vigilance such practices can be arrested, but it is difficult for the British manufacturer to trace the fraudulent imitations which are being passed off under his particular brand in the colonies and foreign countries."

The total exports of Belgian cement during 1906 amounted to £910,928., the quantity being 813,329 tons. The corresponding figures for 1905 were £652,249. and 678,825 tons. In respect of the quantity of Belgian cement sent to the United Kingdom there was a considerable falling-off, amounting to 45,309 tons and £19,294., the 1906 totals being 151,274 tons valued at £169,426. In regard to British colonies the cement exports reached a considerable volume. Australia took 2,498 tons, valued at £2,797. ; Canada, 10,083 tons, worth £11,292. ; Cape Colony followed with 8,055 tons of a value of £9,022. ; India received 8,460 tons, the export value being £9,479. ; Natal, 8,714 tons, worth £9,760. ; and the Straits Settlements 2,562 tons of a value of £2,869. In addition to the above the exports of Belgian cement to Egypt amounted to 37,487 tons and £41,985. Not only did the exports to the United Kingdom fall off in 1906, but those to British colonies also declined in every case, some of the decreases being considerable. It is difficult to explain this lesser demand from British possessions for Belgian cement, unless it is that buyers are beginning to realise that much of the cement manufactured in Belgium, described as "Portland" cement, and bearing British marks and brands is not the genuine article, but is in every sense inferior to the British production, and in many cases is not entitled to be called "Portland" cement at all, according to the accepted standard.

The large growth in the Belgian cement export trade in 1906 was not, therefore, owing to a larger scale to British consumers, but the chief augmentation was in the exports to Germany, which country received 121,018 tons. America accounted for 105,414 tons as compared with 49,550 tons in 1905, but it is scarcely anticipated that this trade will be maintained, as the principal causes of its great growth in 1906 were only temporary and caused by a demand considerably in excess of home production in the United States.

Export statistics, however, are no great criterion in regard to the condition of the cement industry in Belgium from the manufacturers' point of view, for although the output and exports may be large it does not necessarily follow that the monetary returns of manufactories are proportionately great It may be of interest, therefore, to give a few brief particulars of the trade at the end of June and beginning of July, 1907.

The state of the cement trade at the time of writing the report was a quietly satisfactory though scarcely a flourishing one, and if the demand from external quarters is not so considerable as is usually the case, on the other hand orders from the home market are above the average. Prices are, however, very low and somewhat lacking in stability ; the margin of profit between the cost of production and sale price is very small, and forecasts are inclined to be gloomy. These remarks refer only to the export trade subsequent to May, 1907, up to which time there had been a considerable augmentation. Chroniclers of the cement industry appear to take a somewhat pessimistic view of the present situation, which seems scarcely warranted by the output of cement, the orders received and the promises of future prosperity.

"Portland" cement of Belgian origin continues to have a large demand, while that for natural cement is but small. Belgian manufacturers are looking forward to large orders from the United States consequent on the decision to construct more roads with cement concrete. Portland cement in large quantities is being sold on the home markets ; new contracts from abroad are, however, limited, and the prices very low and apparently likely to remain so.

The decreased demand from the United Kingdom and the colonies, though showing its effect upon exterior trade, does not appear to make any great difference to the totals of Belgian production.

A slight increase in the cement exports took place during the first six months of the present year compared with the figures for the corresponding period of 1906, but the augmentation is insignificant compared with previous years, amounting to only 3,720 tons and £3,500. The statistics for the first half of the present year show that 384,075 tons, worth £308,720., were exported, the 1906 figures corresponding to these being 380,355 tons, valued at £305,160.

The particulars which are given in the previous paragraph respecting the state of the cement trade in regard to exports are borne out by the above figures relating to the exterior trade of Belgium. The most remarkable decrease in cement exports is in regard to the United Kingdom. Up to June 30, 1906, 79,949 tons of Belgian cement were sent to the United Kingdom, whereas up to the same date in the present year only 42,397 tons have been sent to Great Britain and 6,730 tons to Ireland, or a total for the United Kingdom of 49,127 tons—a falling-off of over 30,000 tons in the half-year. The exports to Germany decreased considerably, falling from 66,325 tons in 1906 to 55,272 tons in 1907. The United States also purchased less cement than in the first half of 1906, when the figures were 41,332 tons and they have dropped in 1907 to 39,834 tons. The demand for Belgian cement for Chile was greatly accentuated, which kept up the total export figures to their usual standard, but it is scarcely likely that this market will be a lasting one. There was also a considerable increase in the exports to the Argentine Republic, the total of which reached 59,866 tons.

This is one of the first periods for many years that the United Kingdom has not been by far the largest buyer of Belgian cement in the world.

The following table shows the principal exports of Belgian cement during the years 1905-06 :—

	1905.		1906.	
	Quantity.	Value.	Quantity.	Value.
	Tons.	£	Tons.	£
United Kingdom ..	190,583	188,720	151,274	169,426
Argentine Republic ..	66,192	63,548	89,801	100,644
Cape Colony	10,246	9,844	8,056	9,022
Canada	12,172	11,692	10,083	11,292
Brazil	41,911	40,240	45,956	51,470
Egypt	24,225	23,264	37,487	41,985
Germany	55,557	53,340	121,018	135,540
Mexico	22,108	21,228	16,180	18,121
Netherlands	79,450	76,270	92,880	104,025
Spain	19,086	18,328	14,247	15,957
United States of America	49,550	47,572	105,414	118,064
Other countries	101,745	98,197	120,873	135,382
Total	678,825	652,249	813,329	910,928

IMPORTS OF CHEMICAL MANURES INTO EGYPT.—The total value of chemical manures imported into Alexandria in 1902 was 12,912*l.*E. ; in 1905 it rose to 56,801*l.*E. and in the past year to 122,709*l.*E. The share of the United Kingdom was 4,003*l.*E. in 1902, 4,136*l.*E. in 1905, and 17,959*l.*E. in 1906. One-half of the demand is supplied by Belgium.

Continental Notes.

IN the *Chemiker-Zeitung*, for August 21, F. M. Berberich and A. Burr continue their paper on the various methods for the determination of the fat in cream. The processes considered in this instalment are the evaporation method of Mats Weibull, Soxhlet's hydrometer method, Wollny's refractometer method, and the methods of Gerber, Sichler, Köhler and Babcock. The authors have come to the conclusion that the Röse-Gottlieb gravimetric method is the most accurate, whether in its original form with one or two extractions, or as modified by Röhrig and Rieter. The Siegfeld method is almost as accurate, and considerably more convenient and rapid. For technical purposes the methods of Gerber, Sichler and Köhler are sufficiently good, but they are not accurate enough for laboratory use.

In the same issue, Dr. P. N. Raikow describes some simple forms of tubes and cocks for use in the laboratory.

The earliest information concerning Berthold the Black, the reputed discoverer of gunpowder, forms the subject of a paper by F. M. Feldhaus, in the issue of August 24. The writer is decidedly sceptical about the passages in the ancient Chinese classics, upon which is based the claim of the Chinese to have discovered this mixture. He considers that the passages in question really refer to a combustible and not an explosive composition. The European writings within a century of the discovery would appear to justify the conclusion that Berthold discovered gunpowder as well as fire-arms. The military writers of the fifteenth century explicitly ascribe both inventions to the learned German monk of the order of St. Bernard, of the name of Berthold the Black, Master of Arts and Alchemist. The date of the invention was 1380, and eight years later he suffered death on account of his black art. And that is all that we know with certainty about Berthold Schwarz.

The action of ammonium persulphate solution upon cellulose forms the subject of a paper by Dr. Hugo Ditz in the *Chemiker-Zeitung* for August 24 and 28. The writer had observed that when a persulphate solution acidified with sulphuric acid is allowed to act upon cellulose there is a considerable evolution of gas which smells strongly of active oxygen. The recent communication of Cross and Bevan upon the peroxide of cellulose which they found in commercial bleached fabrics induced the author to examine celluloses treated with the acidified peroxide solution, to see if he could detect peroxides in them also. If after the treatment with acidified peroxide solution the cellulose be well washed and a solution of potassium iodide and starch be added, the cellulose is coloured red or blue, showing the presence of peroxide. Ditz found that the peroxide is very rapidly destroyed by boiling with water; two minutes boiling was sufficient to entirely prevent the reaction with potassium iodide and starch. He found also that the treated cellulose contained an acid insoluble both in hot and cold water.

The issue of August 28 also contains an article by Dr. Victor Samter, on the organisation of chemical factories. As regards the labour question the problems are of an entirely different nature to those in engineering factories, about which so much is heard, for the labour is almost entirely unskilled and unorganised. There are, moreover, a great number of different operations to be carried on which differ very greatly one from another. In some of these it is possible to pay the men according to the output, or to give them bonuses on it, but in others, such as the distillation of nitric acid, it is far more important that the operation should be carried out with care than with rapidity. In such cases it may be advisable to give bonuses for yield instead of output, but care must be exercised that the production is not falsified by such means as taking material from the reservoirs and adding it to the material that is supposed to have been just made. As some of the operations carried on are much more important and difficult than others, it is advisable to pay them at a higher rate. But this introduces the difficulty that a man may have to work at several different rates during different parts of the same day. The necessary booking may be simplified by providing each man with a sheet on which the hours are entered that he spends on the different jobs. It is, of course, essential that a record be kept of all goods that enter the factory, and that an analysis be made of all important raw materials. One of the most difficult problems in every commercial or industrial concern is the organisation of a satisfactory method of calculating the cost of production. In chemical works the problem is rendered more difficult by the existence of by-products. When these are of comparatively small value they can be simply booked at the selling price, but when a process produces two materials of almost equal value it is far more difficult. As a basis for the calculation of the cost of production in many factories, sheets are filled up every day with the consumption of the principal raw materials, filter-cloth, etc. A system of giving bonuses to workers for suggestions made is considered. A works chemist requires not only to have a knowledge of chemistry and technology, but also to be a good organiser.

THE INDIAN OILSEEDS CROP.

THE first general Memorandum on the sesamum (til or jinjili) crop of the season 1907-08, has been issued by the Indian Statistical Department.

On the average of the five years ending 1905-06 the total reported area under sesamum in India was 4,899,900 acres, and of that total 70% lay in the provinces dealt with in this memorandum.

The rains in the present season did not begin in the North-central and North-western parts of India till late in July. Sowings of sesamum, which is not a food crop, have therefore been greatly delayed, and the returns of acreage so far obtainable are so incomplete as to render undesirable a general comparison of the figures with those returned at the same date last year. The total area reported in the beginning of August, 1906, was 1,644,600 acres, excluding the United Provinces, which made no definite estimate. The area reported up to the present is 1,442,800 acres, but sowing is in progress over large tracts. The condition of the crop so far is good, though in Bombay there has been an excess of rain.

The following is a summary of the provincial reports. The figures in brackets, following the name of each province, indicate what percentage of the total area under sesamum in British India is ordinarily cultivated in that province.

United Provinces (20%).—There was some rain in the east of the province at the end of June, but general rain did not set in till the end of the third week of July. Good rain has, however, continued since then. In the eastern districts, sowings of mixed sesamum began about the usual time, in the third week of June; elsewhere sowings were only beginning at the date of report (15th August), as food crops had to be sown first. It is therefore impossible to make any estimate of the extent of sowings at this stage. Sesamum is in ordinary practice one of the last crops to be sown, and the area will be governed largely by conditions prevailing in the second half of August.

Central Provinces and Berar (18.5%).—In some of the northern districts rainfall was deficient, and sowings of the early (*Kharif*) crop were in progress at the date of report (10th August). In the remaining districts sowings were successfully carried out, germination was generally good, and the seedlings suffered less than cotton from the long spell of dry weather in June and the beginning of July. Resowing was necessary in certain places. The condition of the young plants is at present satisfactory, and prospects are favourable. The sowing of the late (cold weather) crop had not begun up to 10th August; but there is at present no reason to believe that the total area for both early and late crop will differ materially from that sown last year (808,800 acres).

Madras (17.2%) reports the total area sown in *raiyatwari* villages (about two-thirds of the province) up to the end of July as 212,400 acres, which is about 32% more than the area at the corresponding date of last year. The increase is attributed to seasonable rainfall. The total area reported from villages other than raiyatwari is 11,600 acres, which is about 41% more than that reported at this date last year. The crop is reported to be in fair to good condition.

Bombay (8%) reports the total area sown up to 5th August in British districts and native states to be 324,000 acres, which is about 38% smaller than the area at the corresponding date of last year. Deficient early rains restricted the sowing of the early crop. The late crop is still being sown. The condition of the crop is reported to be fairly good at present, but a break in the rains is desired in places for the late sowings.

Sind (2%) reports a total area of 35,000 acres, which is about 40% below last year's area. Sowings, however, still continue in Upper Sind frontier; elsewhere the decrease is due to insufficient water supply. The crop is in fair to good condition at present.

Panjab (4%) reports 62,600 acres (irrigated 16,600 acres) sown up to the end of July, as compared with 95,500 acres finally ascertained for last year—a decrease of 34.4%, attributed to the failure of the early rains. Sowings, however, still continue.

THE TRADE AND COMMERCE OF MEXICO.

IN his report on the trade and commerce of Mexico for 1906, Mr. Consul L. J. Jerome points out that Mexico has now taken her place among the nations of the world; he also expresses the hope that its mercantile communities will take advantage of this market and not allow it to be monopolised by trade rivals.

The total value of imports in Mexican currency for the fiscal year ended June 30th, 1906, was 220,651,047 dol. 49 c., an increase of £4,200,000. on the previous year. The exports for the same period were valued at 271,138,809 dol. 32 c., and, in the previous year, 208,520,451 dol. 43 c. The total foreign trade showed an increase of £10,506,450.

The table of imports given in the report shows that the import trade of the British Empire to Mexico still takes second place, although, owing to a decrease of imports from the U.K., there was during 1905-1906 a net decrease in the imports from the British Empire of 1,707,638 dol. 97 c. The Americans continue to make strenuous efforts to obtain control of Mexican trade; scarcely a week passes without the country being visited by the representative of some American commercial body. Many of the larger American machinery concerns have branch houses in Mexico, which, added to the proximity of the two countries, gives them an enormous advantage.

The declared value of American imports into Mexico for the fiscal year ended June 30 last amounted to 145,600,131 dol, while those for the whole of Europe were only 72,411,937 dol. The American import trade showed an increase of 45,623,263 dol. over the previous year, whereas that of the whole of Europe showed a decrease of 3,207,401 dol., of which 2,633,661 dol. represents the decrease in imports to Mexico from the United Kingdom and France.

The following table shows a comparison of Mexican imports:

Year.	United States.	United Kingdom.	Germany.
1899-1900	£6,205,283	£2,096,640	£ 1,334,769
1900-01	7,037,991	1,984,910	1,415,990
1901-02	7,806,438	1,653,219	1,290,219
1902-03	8,102,909	2,123,069	1,914,802
1903-04	8,521,754	2,003,230	1,908,216
1904-05	9,997,705	2,164,370	2,045,143
1905-06	14,560,031	2,034,464	2,081,455

The principal imports of chemicals, etc., into Mexico were as follows:—

	July to Dec. 1906.	Fiscal Years. 1905-06.	Fiscal Years. 1904-05.
Animal products ..	£1,001,338	£1,638,683	£1,417,726
Vegetable products ..	1,347,160	3,261,693	3,042,690
Chemical and pharmaceutical products ..	414,549	774,427	707,600
Arms & explosives ..	205,816	412,224	505,376

Amongst the exports were the following:—

	July to Dec. 31, 1906.	Fiscal Years 1905-1906.	1904-1905	1903-1904.
	£	£	£	£
Gold	1,275,660	3,167,578	2,836,188	1,072,644
Silver	4,874,564	12,540,008	6,552,864	7,907,439
Copper	1,333,517	2,865,590	2,980,342	2,323,421
Lead	187,512	496,781	550,466	432,564
Other metals ...	243,311	198,962	111,036	185,895
Dyewoods	20,844	53,509	69,181	84,755

Notwithstanding the imports of gold for minting purposes, and of gold coin, the exports of gold show an increase of £333,389.

The Minister of Finance gives the export of silver as follows:—

	1905-1906.		1904-1905.	
	Dollars	c.	Dollars.	c.
Mexican silver dollars ..	49,671,025	0	1,899,891	92
Foreign silver coins.. ..	123,453	50	77,971	0
Silver slimes	66,043,099	81	53,014,016	12
Silver ore, &c.	9,562,505	46	10,531,766	66
Total value of silver exports .	125,400,083	77	65,523,645	70

This is an increase of 60,000,000 dol. in the value of the silver exports over those of the previous year.

The exports of refined copper (according to Senor Limantour's last statement) were:—

Year.	Quantity. Metric tons.
1901-02	51,507
1902-03	57,220
1903-04	55,582
1904-05	55,578
1905-06	50,914

Copper Ore.—The exports of copper ore were:—

Year.	Quantity. Metric tons.
1901-02	10,366
1902-03	4 911
1903-04	24,704
1904-05	82,169
1905-06	73,475

Lead.—The exports of lead were:—

Year.	Refined. Metric tons.	Lead Ore. Metric tons.
1901-02	98,322	99
1902-03	98,942	29
1903-04	94,028	1
1904-05	97,576	—
1905-06	92,346	1

Sesame.—The ajonojoli, or sesame production, in 1904, amounted to 825,858 gallons.

Indigo.—126,296 lbs. of indigo were produced in 1904, about one-half being produced in Chihuahua and the rest in Morelos and Puebla.

Dividivi.—The production of dividivi, or cascalote, in 1904 was 3,382 tons, the largest amount coming from the State of Michoacan.

Petroleum.—Petroliferous lands extend from the Hacienda of San José de las Ruinas, in Central Tamaulipas, to the district of Valles in San Luis Potosi (where the Ebano oil deposits are being worked) through the counties of Uzuluama, Tuxpam and Papantla in Vera Cruz. Further to the south another region is found which embraces the Vera Cruz counties of Acayucan and Minatitlan, and extends southwards through the States of Tabasco, Campeche, and Chiapas. Petroleum has also been found in small quantities in the Federal district of Mexico, Jalisco, and Oaxaca.

Bituminous asphalt also seems common in parts of the States of Vera Cruz and San Luis Potosi. The Ebano oil is being used as fuel for locomotives by the Mexican Central Railway. The oilfields in Northern Vera Cruz are not yet being operated commercially but are being actively developed. The oil of the field of Southern Vera Cruz, especially that of Minatitlan, is being stored, preparatory to the completion of large refining works, the property of Messrs. S. Pearson and Son, Limited. This Minatitlan oil is said to require considerable refining, being very rich in naphtha; it is the intention, once the oil can be refined to the required degree, to use it as fuel for the locomotives of the Tehuantepec National Railway. These locomotives are all oil burners, but the oil is at present imported. It is also intended to convert the locomotives of the Mexican Railway and of the Vera Cruz and Pacific Railway into oil burners as soon as the Minatitlan refineries are completed. This will cause another decrease in British imports into Mexico. The Mexican Railway now imports its patent fuel and coal for its engines from Wales, but once its locomotives are converted, the importations will cease.

Mining.—The premier industry of Mexico is mining. On account, however, of the wide scope, mining is a most difficult subject to report on. "In the absence of any official data, I have," says the Consul, "been obliged to make my remarks on the subject as brief as possible."

In September, 1906, there were 1,572 gold mines (one-third of these being situated in Sonora), 6,467 gold and silver, 5,461 silver only, 1,373 gold, silver and copper, 1,317 gold, silver and lead, 262 gold and copper, 794 silver and copper, 314 silver, copper and lead, 3,518 silver and lead, 4 silver and manganese, 5 silver and mercury, 52 antimony, 86 sulphur, 1 bismuth, 970 copper (Sonora again being the State in which this metal is the most extensively found), 211 copper and iron, 25 copper and lead, 40 tin, 5 tourmaline mines (all in Lower California), 383 iron mines, 9 manganese, 151 mercury, 21 opals, 94 lead, 6 "sal gema," 1 turquoise in operation in Lower California (an unworked deposit of turquoise exists in Northern Zacatecas) and 49 zinc.

Digitized by Google

COLIMA.

Mining.—There has been very little progress in the mining industry in the State of Colima in the past two years. Discoveries of large bodies of iron ore have been made, and these are said to be not only very extensive but of very good quality. The ore occurs in the form of magnetite and hematite.

Several new discoveries of copper ore are also reported, the assays from which run very high. These ores occur as malachite, azurite, chalcocite, chalcopyrite, and black oxide of copper. There have also been reported two discoveries of lead ore in the form of galena and cerussite. Manganese and graphite are claimed to have been discovered, but so far not verified. There has been very little intelligent prospecting done in the past two years, and no mining. The coast range of mountains is almost unexplored.

The Mexican Central Railway has surveyed and is projecting a branch line from Colima to Autlan, some 80 miles to the north. This line will open up a very rich copper district where there are already several shipping mines, although they have to send their ores on muleback some three days' journey over the mountains to the railroad.

Alcohol.—Alcohol is manufactured at the different sugar factories and is said to be a very profitable business, but is hampered by lack of transport; annual production 262,000 litres, worth 23c. per litre.

Indigo.—The growing of indigo anil and the making of dye has gradually died out in the State, and what was once a flourishing industry is now almost at an end; annual production, 10,000 kilos., worth about 3 dol. per kilo.

Palm Oil.—The palm trees which produce palm oil are the most easily cultivated and prolific of the palm trees. There is a steadily increasing demand for the oil, more especially for the manufacture of soap. The trees begin bearing at five years of age and from seven years of age on bear indefinitely. Practically no cultivation is required. Annual production, 283,000 kilos., worth 42c. per kilo.

LOWER CALIFORNIA.

Exporters should note that all quotations must be made c.i.f. San Francisco. Goods should be shipped in bond on Mexican papers. If this is done a buyer can immediately figure the cost of the goods laid down in Ensenada. The American method is very different to the British, no mention being made of cash except to say that prices quoted are subject to so much extra discount. The American knows the financial standing of the purchaser. If this is not satisfactory he does not ship the goods; he will not, however, insist on payment in full unless the credit is bad.

Mining.—The mining industry within this Vice-Consular district is at last coming to the fore. It has been in a chaotic condition for a number of years, but is now being carried on for production. For years the northern district of Lower California has been subjected to the speculator and the promoter, the country has been exploited by the "graphite and sidewalk" methods, and the promoters have pencilled out some large profits "on paper." Legitimate mining money could not be induced to even look at property if it was situated in the northern district of Lower California.

At present miners are making large investments in both gold and copper properties. A considerable amount of work has been done on the copper properties about 200 miles south of Ensenada, and the showing has warranted the erection of a smelter, and the owners are very well satisfied with the results and give a very good report of the outlook in the mine. Capital from British Columbia has already been invested to an amount exceeding 200,000 dol.

MAZATLAN.

Mining.—Mining is the principal industry of this State, but it is in its infancy, being kept back through lack of means of transport. Only ores of very high value can afford to pay the heavy charges of freight to the coast, in many cases 100 dol. a ton. The system of treating the ores is by means of cyanide; also lixiviation. One up-to-date plant with tube mills has just been erected at Copala by a British company, which is a great success. All the ores exported go to the United States. The following table shows the value of metal exported in bar and ores:—

Gold	$1,567,566
Silver	3,328,500
Copper	120,130
Zinc	14,530
Lead	8,120
Total	$5,038,846

MONTERREY.

Mining.—As this city depends very largely upon the mining industry, the condition of the mines in this and the neighbouring States of Coahuila and Tamaulipas affects its prosperity to a large extent. During the past year there has been a great boom in zinc mining, many old and abandoned lead and silver mines having been reopened and are now being worked at handsome profits. The zinc ores are all exported to the United States of America.

SOCONUSCO.

Mining.—There is one mine near Exquintla, but it has been abandoned for years. In the adjoining department of Motozintla prospectors are finding rich indications, and several denouncements have been made. Probably a company will be formed soon to explore the locality; the distance from here is about 65 miles over very bad roads.

Rubber.—Rubber, on the other hand, is having quite a boom. There are several large plantations opened up here already, and clearing is going on now for planting up new ones this year The native tree, *Castiloa elastica*, is what is being planted up and the soil, climate, etc., seem to be exactly suitable. These plantations belong principally to American companies. Tapping will probably begin this year on the older plantations, when some accurate idea may be formed of the production. Rubber has not been cultivated before in these parts on an extensive scale, and the results are being carefully watched by all interested in this cultivation.

TAMPICO.

The import of chemical goods at Tampico during 1905-06 was as follows:—

U.S.A.	£74,241
Germany	30,209
U.K.	56,455
France	19,739
Spain	2,496
Belgium, ...	1,097
Italy	1,558
Austria-Hungary	46
Netherlands	—
Switzerland	967
Other European Countries ..	456
Canada	227
S. America	3,266
Asia	7
Africa	—

VERA CRUZ.

The principal articles of import at Vera Cruz for the years 1903-1904 and 1905-1906 were:—

	1903-1904.	1904-1905.	1905-1906.	Increase. 1904-05.	Increase. 1905-06.
Cotton, woollen & linen yarn & textiles	£ 1,110,473	£ 1,112,555	£ 1,896,429	£ 2,082	£ 783,874
Chemicals & drugs	270,405	283,271	534,625	12,866	251,354

The exports at Vera Cruz for the same period were as follows:

	1903-1904 Tons.	1903-1904 Value £	1904-1905 Tons.	1904-1905 Value £	1905-1906 Tons.	1905-1906 Value £

MINERAL OILS IN ITALY.

THE reduction of the tax on petroleum and other mineral oils from 48 lire (£1. 18s.) to 24 lire (19s.) per hectolitre (22 gallons) is, in the opinion of the British Consul-General in Italy one of the greatest benefits to the community which could have been conferred by the Finance Minister. It is especially a boon to the poorest class, to whom mineral oils have become the only illuminant, and who felt severely the crushing nature of the tax. The same reduction will apply to varnishes containing mineral oils, which will benefit trade by making them considerably cheaper. It will also have the effect of reducing the cost of running automobiles and motor boats, both of which have been handicapped by the price of the fuel. This will cause a considerable increase in the output of these machines, which are now being so extensively manufactured in Italy. A certain amount of petroleum is found and refined in Italy itself, and this has hitherto paid a tax of 10 lire (8s.), which tax will be abolished. All contracts for lighting by mineral oils will be reduced by the amount of the tax. It is calculated that the stock of oil in Italy which has paid the higher duty is practically exhausted, so the reduction in price began to take effect on April 1, 1907. Enormous as is this reduction, there can be no doubt that it is sound policy, and that it will be followed by an equivalent increase in consumption, which will in the end more than compensate for the initial loss. Petroleum was first taxed in Italy in 1864, when a duty of 2 lire per hectolitre (22 gallons) was imposed. This was increased from time to time, till in 1901 the tax had become 48 lire (£1. 18s.). The fall in consumption was heavy, but this was largely caused by the introduction of acetylene gas and electric light. The home production amounts to 64,000 hectolitres (1,408,000 gallons).

CASEIN.

(*To the Editor of the Chemical Trade Journal.*)

Sir,—"Liverpool Inquirer" has seen articles made from "Galalith," a celluloid-like compound from casein and formaldehyde. This material was invented by Messrs. Adolf Spitteler and W. Krische, and is already manufactured in very large quantities by the Vereinigte Gummiwaren-fabriken Harburg-Wien, in their factory at Wimpassing, near Vienna.

Yours, etc.,

12, Mark Lane, London, E.C. OSCAR GUTTMANN.

(*To the Editor of the Chemical Trade Journal.*)

Sir,—The enclosed clipping is from your *Journal*. We are manufacturers of casein, and shall be very pleased to give your correspondent any information he may wish in regard to same. The manufacture of solids of casein is not a new idea by any means, but the industry is principally in the hands of one very large concern who consume enormous quantities of casein. The firm referred to is the Gallalith Company of Germany, France, and Austria. Their products are manufactured by patented process.

Yours, etc.,

Sheepcote Lane, Battersea, London, S.W. CASEIN, LIMITED.

CHANCERY OF LANCASHIRE.

(*Before the Deputy Chancellor.*)

THE BLEACHERS' ASSOCIATION, LTD. *v.* J. A. YOUNG.

On Wednesday last, at the Vacation Sitting at Liverpool of the Chancery Court of Lancashire, the Bleachers' Association applied for an interim injunction against James Albert Young for breach of covenant.

Mr. Bather, for the plaintiffs, said that in 1900 the Association took over the business of John Young and Co., who were bleachers at Manchester. The defendant was one of the persons interested, and he was paid £2,000., in consideration of which he agreed that during a period of twenty years he would not, as manager, agent, director or servant, directly or indirectly, engage in the business of a bleacher, or allow his name to be used in connection with any such business, except that of the plaintiffs, within the United Kingdom. From that time until March, 1906, he acted as assistant manager or manager at the works where the business of John Young and Co. had been carried on. It was then found that he was taking part in the promotion of the Culcheth Bleaching and Dyeing Company at Newton Heath, and he was discharged from the service of the plaintiff company. He had since taken an active part in the Culcheth Company's business and obtained orders for the bleaching of goods. It was alleged that while in the service of the Association he induced some of their workpeople to agree to enter the employment of the Culcheth Company.

These allegations were denied by Mr. Young in an affidavit which was read by his counsel, who contended that the covenant was void, the area being too great and the time longer than was necessary.

The Deputy of the Chancellor granted the interim injunction asked for.

NITRATE OF SODA.

THE market remains comatose, with a drooping tendency; at this time last year it was very active at advancing prices, 9s. 5d. per quintal, f.o.b., being freely paid for prompt shipment, compared with the present nominal quotation of 8s. 11½d. According to a leading trade circular, "anxious sellers are very few, and any serious buying would raise values again," but the *desideratum* is conspicuous by its absence. This is, perhaps, hardly to be wondered at, considering that stocks in Chili reach 560,000 tons, while the September-October output of not less than 320,000 tons will further be available for shipment by the end of the year! All the European ports are crowded with nitrate, Hamburg having 45,000 tons against 14,300 tons a year ago, and Dunkirk 29,000 tons against 13,000 tons. The large chemical works on the Rhine should have no difficulty in filling their requirements on favourable terms, as 12,000 tons have just arrived at Rotterdam, and three more large direct cargoes are shortly due there. Tonnage is plentiful on the West Coast, there being 90,000 tons register disposable, and chartered ships are arriving freely at the nitrate ports. The best chance for the market would appear to be another lock-out at Iquique or labour troubles on the "pampa."

SUPERPHOSPHATE.—Negotiations are taking place in Vienna with a view to the renewal of the Superphosphate "Kartell," so desirable on account of the great advance in the price of the raw material. The German manufacturers are agreeable, but the Austrian producers, being better supplied with Algerian and Tunisian phosphate, seem to be holding back.

THE DAILY PRESS AND FIRES AT CHEMICAL WORKS.—On Friday week an outbreak of fire occurred at the Hull works of Messrs. Major and Co., Ltd. A certain amount of damage resulted, but the fire was practically confined to one department, and the execution of orders and the receiving of goods, etc., will be in no way affected, while the damage is fully covered by insurance. In reporting this fire, several of the daily papers dealt with the matter in a very sensational manner, and from one of the reports now before us it would appear that the writer had exhausted his vocabulary in his attempt to produce a realistic but exaggerated description of a chemical works fire. It is greatly to be deprecated that liberties should be taken with the facts in transmitting reports of this description to the general public, and it would certainly be advantageous if such highly coloured productions were rigidly scrutinised before publication.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Extraction of Copper and other Metals from Pyrites. G. B. Ellis, of Mewburn, Ellis and Pryor, 70 and 72, Chancery Lane, London (communicated by Les Produits Chimiques de Croissy, 82, Rue St. Lazare, Paris). British Patent 17,441. August 2, 1906.

The roasted pyrites are mixed in a dry state with 2 to 5% of commercial chloride of lime, or they are moistened with solutions of hypochlorites of alkalies or alkaline earths containing a like quantity of available chlorine. The mixed ore is then introduced into vats where it is sprayed with an excess of dilute sulphuric or hydrochloric acid and warmed. If lead is present in the ore it is preferable to employ hydrochloric acid. The reaction is allowed to proceed for 12 to 24 hours; the liquors are then drawn off, and the residue washed with luke-warm dilute acid and then with water. The iron residues are then practically free from foreign metals.

The inventors observe that they are aware that solutions of hypochlorous acid, chloride of lime or other hypochlorites and acids, with or without the addition of nitrate of soda, have been employed for the extraction of gold and other metals from ores, but under conditions calculated to produce *aqua regia*, or hypochlorous acid as the solvent reagent, but the object of the present invention is not to generate hydrochlorous acid, but to rely on the selective action of free chlorine in acid solutions for the separation of copper and other foreign metals contained in roasted pyrites from the oxide of iron.

Improvements in Gas Producers. H. Becker, 131, Osborne Road, Pontypool. British Patent, 18,981. August 11, 1906.

This invention relates to improvements in gas producers of the kind in which the coal or coke is charged into a body lined with fire-bricks, and provided at its lower end with a grate on which the incandescent fuel rests, and through which air, or air and steam, is drawn or driven. The inventors observe that such gas producers as heretofore made possess a number of disadvantages in practice, amongst which may be mentioned the fact that it is extremely difficult to properly regulate the even combustion of the fuel, that the fuel frequently, due to the extreme heat, cokes in large hard lumps, and that the ashes fuse and form irregular clinker, which is difficult to manage and prevents the fire burning evenly, and at the same time also forms spaces which prevent the carbonic acid gas from coming into intimate contact with the incandescent fuel, the gas blowing through and causing a yield of poor gas. Moreover, owing to the intense heat, the ashes fuse with the hot bricks of the lining and form hard projections, which restrict the area of the incandescent zone and prevent the coal from dropping, reducing the quantity of the gas and prejudicing its quality.

The present invention has for its object to obviate these disadvantages, to which end provision is made for dispensing with the firebrick lining. In carrying out the invention a producer is constructed comprising an outer iron shell of cylindrical, square or other suitable shape, and arranged vertically over a trough filled with water, the water forming a seal. Within this shell is arranged a cylindrical or other suitably shaped body of metal, which is open both at the top and bottom, the body being either supported or suspended within the shell and placed at such a height that its lower open end is above the level of the water in the trough. This cylindrical or other body has no grate or perforations, and is furnished with an external jacket providing an annular space around the body for the reception of a supply of water for the purpose described later. A space is left around the water-jacketed body between it and the external shell, this space being provided with inlets for the supply of air. The upper end of the internal body and external shell are hermetically closed by means of a wall of brick, at the top of which is situated the charging opening for the fuel, and which is also provided with a lateral outlet for the gas obtained. The annular jacket around the internal body is filled with water, the annular space being closed at its lower end and open at the upper end.

In a modified construction of the apparatus the upper end of the annular boiler does not directly open into the air space surrounding it, but is closed and is provided with an external outlet pipe conveying the steam generated into the air inlet or air space. The operation of this form of the apparatus is, however, in other respects, the same as that above described.

A sheet of drawings shows the construction.

Improvements in Electrolytes for the Electro-deposition of Copper. S. O. Cowper-Coles, Grosvenor Mansions, Victoria Street, Westminster, London. British Patent, 20,380. September 13, 1906.

This invention has for its object to provide an electrolyte from which the copper deposited is smoother and of a better quality than hitherto. To an electrolyte of ordinary composition the inventor adds varying quantities of aluminium sulphate. He has found in practice that by employing an electrolyte composed of copper and aluminium sulphate and sulphuric acid when large current densities are employed, the quality and smoothness of the copper are considerably improved. For example, with a solution containing about 12% of copper sulphate and 12% of free sulphuric acid, it is found that the addition of about 1% of aluminium sulphate is of considerable advantage when working at a temperature of about 65° C. The inventor is aware that it has been proposed to add a salt of aluminium, such as the sulphate, to the solution of a metal, such as copper, to be electro-deposited, the object being to obtain a deposit containing a quantity of aluminium, that is to say, an alloy. In the case of

Digitized by Google

the present process the aluminium sulphate is added in such proportion and under such conditions that no deposit of aluminium is obtained, the addition of the salt acting, as above stated, merely to improve the quality of the copper deposited.

Electrometallurgical Process for Extracting Copper from its Ores. L. Jumau, 18, Rue Mogador, Paris. British Patent, 27,120, 1906. (Date claimed under International Convention, November 29, 1905.)

The claims are :—(1.) A process for extracting copper from its ores, which consists in dissolving the copper of the ore in an ammoniacal solution, electrolysing the solution thus obtained in presence of a sulphite, either directly or after precipitation and re-dissolution of the copper and reduction of the new solution by treatment with sulphur dioxide, and recovering the ammonia and sulphur dioxide used in the process.

(2.) In the process referred to in Claim (1), leaching the ore with a solution of ammonia mixed with ammoniacal salt, preferably ammonium sulphate or sulphite. (3.) In the process referred to in Claim (1), reducing to cuprous salts the cupric salts in the ammoniacal solution which contains the copper of the ore, whether as a result of direct leaching of the ore or of re-dissolution of the copper oxide precipitated by evaporation of the solution obtained by leaching the ore, by passing a current of sulphur dioxide into the said ammoniacal solution. (4.) In the process referred to in Claims (1) and (3), deriving the sulphur dioxide from the roasting of the sulphide ores, when these are the ores under treatment. (5.) In a process for extracting copper from its ores wherein the copper in the ore is dissolved in an ammoniacal solution which is then electrolysed either directly or after precipitation and re-dissolution of the copper and reduction of this new solution by sulphur dioxide, conducting the electrolysis in presence of a solution of sulphite as a depolariser at the anode, such solution being the ammoniacal solution reduced with sulphur dioxide, or a solution of basic, neutral, or acid ammonium sulphite. (6.) In the process referred to in Claim (1), recovering the ammonia contained in the solution after the electrolysis, by treating such solution with an alkaline earth, such as lime, or the ore itself, if this is capable of playing the part.

Improvements in or Relating to Apparatus for Concentrating Sulphuric Acid. A. J. Boult, 111 and 112, Hatton Garden, London (communicated by L. Stange, 84, Bismarck Strasse, Aix-la-Chapelle, Germany). British Patent, 91 January 1, 1907.

This invention relates to improvements in apparatus for concentrating sulphuric acid of the type in which the concentration is effected in cast-iron pans by blowing hot air over the surface and by heating the pans. The cast-iron concentrating vessel is provided with means for blowing heated air over the surface of the liquid in the vessel, and with means for heating the outside of the upper vessel. The vessel has a conduit near its lower end, which communicates with a chamber beneath, and means are provided for cooling the chamber for the purpose of preventing incrustations. An inner vessel, having an opening at its lower end, is suspended within the upper part of the containing vessel, and is formed of acid-proof stoneware, the arrangement being such that the dilute acid passes down through the stoneware inner vessel and only when concentrated passes into the space between the inner stoneware vessel and the outer cast-iron vessel. The lower chamber, which is cold and which receives the precipitate from the containing vessel, is provided with a valve-controlled opening for the discharge of the precipitate therefrom. The original specification should be consulted.

Improvements in Process for Treating Ores Containing Zinc Sulphide and Lead Sulphide. J. Thelberg, 45, West 32nd Street, New York, U.S.A. British Patent, 2,789. February 4, 1907.

The inventor claims :—(1.) The process of producing oxide and sulphate of zinc and sulphate of lead, which consists in forcing a superheated mixture of steam and air into a body of ore containing zinc sulphide and lead sulphide in a furnace. (2.) The process of producing a pigment from ores containing zinc sulphide and lead sulphide, which consists in placing a layer of refractory material on the bottom of a furnace, charging the mixture with said ores, then forcing the superheated mixture of steam and air through the refractory material from beneath into the charge in said furnace, which ignites and oxidises the sulphur, zinc and lead, then conveying the formed volatilised oxide and sulphates, together with the gases, out of the furnace, cooling the gases, the volatilised oxide and sulphates to a suitable temperature, and separating the condensed oxide and sulphates from the gases. (3.) In the process claimed in Claim (2), using the product evolved for the production of sulphuric acid, substantially as specified. (4.) The art of producing white pigments from ores containing zinc sulphide and lead sulphide, as specified in Claim (1), which consists in charging a furnace with said ores, adding a quantity of quick lime to the charge of ores, and then forcing a superheated mixture of steam and air into the furnace. (5.) The process of producing a pigment from ores containing zinc sulphide and lead sulphide, according to Claims (2) and (3), wherein a quantity of the cooled and separated gases, consisting mostly of nitrogen and sulphur dioxide, are introduced into the furnace above the oxidation zone, for regulating the temperature in that part of the furnace, as specified.

Two sheets of drawings show the construction of the apparatus.

Process of Continuously Producing Carbide from Lime and Carbon. A. Petersson, Alby, Sweden. British Patent, 5,658. March 8, 1907.

The claims of this specification are :—(1). The process of continuously producing carbide in an electric furnace, which consists in charging carbon and lime separately into the furnace in such a manner that separate upright columns of said materials in close contact with each other are maintained in the furnace, leading an electric current through the column of carbon for heating the same to a point sufficient for forming carbide with the lime, and burning the combustible gases formed during the reaction in the column of lime for preliminary heating the same. (2.) The process of continuously producing carbide in an electric furnace, which consists in charging carbon and lime separately into the furnace in such a manner that separate upright columns of said carbide forming materials in close contact with each other are maintained in the furnace, leading an electric current through the column of carbon for heating the same to a point sufficient for forming carbide with the lime, removing the combustible gases formed during the reaction through the column of lime and introducing air into the said column of lime for burning the said combustible gases for preliminary heating the lime charge.

A sheet of drawings accompanies the specification.

A Process for Manufacturing a Fertiliser from Atmospheric Nitrogen. L. Rot', Cauth, near Breslau, Germany. British Patent 12,74'. June 1 1907.

In this process air is passed through a fixed porous resistance into a moist mixture consisting of clay, iron, lime, sand, and magnesia, to which, during the operation, an ammonia-fixing means, such as sulphate of iron or sulphuric acid, is added.

YORKSHIRE DYEWARE AND CHEMICAL CO., LTD.—The report for the year to June 30 states that during the past year a scheme for the reduction of the capital was placed before the shareholders, and resolutions necessary for carrying this scheme into effect were passed practically unanimously. This scheme, which received the sanction of the Court on May 14, provided for the reduction of the capital by the cancellation of the whole of the 80,000 ordinary shares, all of which were held by the vendors, and the writing down of the 100,000 preference shares by 5s. per share, being a total reduction of £105,000., leaving the present capital, as reduced, at 100,000 shares of 15s. each. This reduction has enabled the directors to write off absolutely the whole of the deficiency on profit and loss account as on July 1, 1906, to cancel the whole of the goodwill, and to considerably reduce the valuation of the buildings, plant and machinery where necessary. The advisory committee, appointed at the meeting of shareholders held in January last, have worked in co-operation with the directors, and have rendered useful services to the company. The directors are quite satisfied with the progress which has been made by the company during the past twelve months, especially in consideration of the fact that it is only during the past four or five months that the beneficial influences of centralisation have commenced to make themselves felt. After providing for depreciation of property, plant and machinery, and all other charges, except directors' remuneration, the trading for the year has resulted in a profit of £12,070. The following payments have to be deducted, viz. : Interest on debenture stock, £4,873. ; directors' salaries and commission, £2,941., leaving a profit on the year's trading of £4,254. The directors recommend that this balance shall be dealt with as under :—Payment of a dividend at the rate of 2½% £1,781. ; transfer to reserve fund, £2,000. ; carry forward to next year, £473.

J. MANDELBERG AND CO.—The directors have declared an interim dividend on the ordinary shares at the rate of 10% per annum for the half-year ended June 19 last. The usual interim dividend has hitherto been at the rate of 8% per annum.

CAMPHOR AND RUBBER IN INDIA.—The United Provinces Forest Department are experimenting with the cultivation of the camphor tree in the forest tracts of Siwalah, and lac propagation is being carried out in the same locality, where it is intended to extend its cultivation. The Madras Forest Department are experimenting with Japanese camphor at Vizagapatam, where some of the plants raised are thriving vigorously. The same department is experimenting with rubber, and the following species are under cultivation:—Landolphia Florida, Ceara, Ficus Elastica, Para, Kicksia Africanus, and Dichopsis Elliptica. Cultivation is in progress in North and South Malabar, South Canara, Kistna, the Nilgiris, Coimbatore, and Tinnevelly.

THE RUSSIAN CHEMICAL MARKET.

REPORTS from Odessa show no change in the general situation. There is a better demand for disinfectants in view of the spread of cholera. The prices of all items are firm. Ammonia is quoted 7 roubles 20 copecks to 7r. 35c. per pood of 36 lbs.; crystallised borax, 4r. 75-80c.; white lead, 6r. to 6r. 10c.; zinc, white, 19 to 20r., in casks of 3 poods (about 112 lbs.); sulphate of copper, 6r. 80-95c.; English sal ammoniac, lumps, 8r. 40c.; Caucasian potash, 2r. 50c.; Saratoff ditto, 2r. 70-80c.; caustic soda, 2r. 80c.; calcined soda, 1r. 40c.; Russian tannin, 37r. 50c. to 38r. 50c.; foreign ditto, 41 to 42r.; bichromate of potash, 9r., all per pood.

The fortnightly chemical report from St. Petersburg up to September 3 states that throughout the whole summer nothing particularly notable has occurred on the chemical market there. It has been governed by the state of the foreign markets on the one hand and by the colourless disposition of local trade on the other. Nitric acid, 36° B., is quoted 3 roubles to 3r. 20 copecks; crystallised borax, 4r. 30-70c.; white lead, 5r. to 5r. 15c.; sulphate of copper, 6r. 60-65c.; Saratoff potash, 2r. 65-75c.; Chili saltpetre, 1r. 90c. to 2r.; caustic soda, 2r. 65c.; superphosphate (16-17%), 65-70c.; red lead, 4r. 80c. to 5r.; bichromate of potash, 8r. 40-50c.

The Warsaw market for the same period has been without special feature. Quotations are: Nitric acid, 36° B., 3r. 40c.; borax crystals, 4r. 90c.; white lead, 5r. 80c.; sulphate of copper, 7r. 35-65c.; red lead 5r. 50c.; acetic acid (60%), 5r. 44c.; bichromate of potash, 9r. 75c., all per pood.

LITIGATION IN THE SOAP TRADE.—It is reported that a further action is pending in connection with the recent proposed soap trade combination.

Digitized by Google

BABUL GUM, found in Madras forests, is officially used by the Indian Government Stationery Department for office use.

PARTNERSHIPS DISSOLVED.—The *London Gazette* contains the following announcement of dissolutions of partnerships:—Walter James Saville, William Marvel, and Walter Goodwin Saville, drysalters, paint, colour and varnish manufacturers, 94, Great Ancoats-street, Manchester, as Saville, Marvel and Co., and Hambourgh Colour U. Chemische Fabric. Thomas Ingham, Ephraim Thornber, and William Thornber, as Thornber Son and Co., Padiham, manufacturing chemists, as regards T. Ingham.

NEW LANCASHIRE MAGISTRATES.—A list of new names added to the Commission of the Peace for the County Palatine of Lancashire contains the following:—James Bennett Aitken, chemical manufacturer, Penketh-by-Warrington; Max Muspratt, director of the United Alkali Company, Liverpool; John Bryson Orr, chemical manufacturer, Woolton, Liverpool; Austin Townsend Porritt, woollen manufacturer, Stubbins, near Manchester; Robert Pearson Skelton, paper manufacturer, Remsbottom; Joseph Herbert Wild, paper maker, Stand, near Manchester.

REPORTED ATTEMPT "TO CORNER THE WORLD'S SULPHUR."—A New York correspondent of the *Manchester Guardian* says:—"A despatch from New Orleans states that the Rockefeller interests controlling the United States Sulphur Company are preparing to control the world's supply of sulphur and will make New Orleans the greatest brimstone port in the world. Hitherto there has been an arrangement with the Italian producers respecting the distribution of Louisiana sulphur. In consequence shipments to Europe have been small, but the arrangement has now been terminated, and American sulphur is to be heavily exported, particularly to France and Germany. The United States company controls all the American trade, and has largely accumulated stocks, which will be placed on the market in sharp competition with the Italian producers."

Market Reports.

THE AMERICAN CHEMICAL MARKET.

NEW YORK, Aug. 27, 1907.

(Rate of Exchange, $4.87 = £1.)

Nitrate of soda is dull; no sales of consequence have been reported this week. Prices, however, are firm at $2.45 per 100 lbs. Sulphate of ammonia is also rather dull in the local market, but the prices are well maintained in sympathy with nitrate. Grey muriate of ammonia for galvanising is unchanged, at 5¼c. to 6¼c. per lb.; white electrical is rather dull, and is quoted as low as 5¼c. per lb. Lump sal ammoniac, 9¼c. per lb. Lump carbonate of ammonia is rather dull, very little new business being reported, although it is moving nicely on contract at 7¾c. to 7¾c. per lb. Bleaching powders are quoted at $1.30 per 100 lbs. Sulphate of copper is weak, and reductions in prices are expected; it is held at present at 7c. per lb. White powdered arsenic is selling on spot at 7¾c. per lb., while futures may be bought from 7c. to 7¼c. per lb.; a few good sales have been reported. Red Saxony arsenic is selling at prices quoted previously. Calcined carbonate of potash, 80-85%, is in pretty good demand, and prices are well maintained at 3¾c. to 3¾c. Hydrated carbonate of potash is also in fair request, and is selling on spot at 4¾c. Caustic potash, 75%, is moving along rather freely on contract; prices are about the same, that is, 5¾c. per lb. Chlorate of potash and soda remain unchanged; prompt deliveries fetch 9¼c. per lb. Bichromate of potash is in rather good demand, and is selling at 8¼c. to 8¾c. per lb. Bichromate of soda is quoted at 7¼c. to 7¼c. Oxalic acid is rather weak; some sales have been reported at $8.45 spot, and for next year at 6¾c. to 7½c. per lb.

TAR AND AMMONIA PRODUCTS.

FRIDAY.

Benzols quiet, with quotations given at 8¼d. for 90's, and 9d. to 9¼d. for 50-90's. Crude tar, 15s. 6d. to 20s. per ton, Thames; 1¼d. to 1⅝d. per gallon, delivered. Refined tar, 12s. per barrel; Gas Company, 12s. 6d. Pitch, 27s., f.o.b.; Gas Company, 20s.; East Coast, 25s. 6d. to 26s.; West Coast, 24s. to 25s. Refined naphthalene, £6. 10s. to £8. 10s. Toluol, 90%, 10½d. to 11d.; pure, 1s. 3d. Carbolic acid, crude, 50%, 1s. 5½d. to 1s. 5¾d. 60%, 1s. 8¼d.; 75%, 1s. 11¾d. to 2s.; crystals, 39-40, 5¾d. 34-35, 5¼d. Cresylic, 95%, 1s. 1d. to 1s. 1¾d. Anthracene 40 to 45 per cent. A, 1½d. to 1⅝d. Pyridin, 4s. to 4s. 3d.

Sulphate of ammonia: Nearest values are:—Beckton, £12. 1s. 3d.; next years, £12. 2s. 6d.; Beckton terms, £11. 11s. 3d to £11. 12s. 6d.; London, £11. 15s. to £11. 16s. 3d.; Hull, £11. 15s.; Liverpool, £11. 17s. 6d.; Manchester, £11. 15s.; Leith, £12.; and forward, £12. 5s.

Nitrate of soda, ordinary, 11s. 3d., and refined, 11s. 9d. Liverpool, ordinary, 11s.; refined, 11s. 1½d. Official quotations—Cargoes, off coast or due, 11s. 1½d.; ditto, for prompt shipment, 11s. 6½d.

THE LONDON METAL MARKETS.

THURSDAY.

Copper: Standard brands, £68. to £68. 5s. cash, and £68. 10s. to £68. 15s., three months. Tin: G.M. quality, £166. to £166. 10s. cash, and £165. 5s. to £165. 15s. three months; English, £169. Lead: soft foreign, £20. 5s. prompt, and December £19. 10s.; English £20. 10s. to £20. 15s. Spelter, ordinary brands, £20. 10s. to £20. 15s., ex ship; hard, £17. 10s., f.o.b. Antimony £38. to £40.; ore, £10. 10s. to £11. Bismuth, 6s. 0d. Quicksilver, £7.; seconds, £6. 16s. Nickel, 1s. 10d. per lb.

FERTILISER MATERIALS.

THURSDAY.

Quietness still prevails in all markets, but, notwithstanding this, prices are well maintained.

Raisers of all grades of mineral phosphates being so well sold ahead, and being closely occupied in fulfilling contracts, show little disposition for further business, and any transactions done are at extreme prices.

Nitrate of soda is very quiet, but prices remain steady on spot, at 11s. 1½d. to 11s. 4½d. per cwt., ex store, for ordinary and refined qualities respectively.

East Indian bone meal is neglected, but shippers are firm at £4. 17s. 6d. per ton, nett, c.i.f. terms, Liverpool, 4½ and 52% quality. On spot, £5. 5s. to £5. 10s. per ton, according to quality, ex store, is asked.

MISCELLANEOUS CHEMICAL MARKET.

FRIDAY.

The demand for sulphate of copper continues quiet, and with further decline in the metal, quotations are again lower. To-day's price is nominally £25. 5s. to £25. 10s., and for spring shipment £24. 10s., f.o.b. Liverpool. Bleaching powder, softwoods, is steady at £4. 7s. 6d. on rails, for spot delivery, and £4. f.o.r. is still quoted for 1908 contracts. Caustic soda and ammonia alkali are unchanged. Chlorates are dull. There are a few forward enquiries for saltcake, and quotations rule at same level as for this year, viz.: 40s., carriage paid. Recovered rock sulphur, £4. 10s., f.o.r. Soda crystals and bicarbonate are without alteration. American brown acetate of lime slow of sale and price easy at £8. 7s. 6d., c.i.f.; grey, £12. 10s. per ton. Acetate of soda quiet, at £16. 15s., ex ship. Lead salts are in fairly good request, but prices have a downward tendency. The price of white powdered arsenic is well maintained at £31. Garston, and business is moderately brisk. Prussiates continue weak, and potash is offered at 5¾d. to 5¾d. Soda, 3¾d. to 3¾d. per lb. Oxalic acid steady at 3¾d. to 3¾d. for spot delivery. Potash, caustic and carbonate, are very scarce for prompt, and prices have further advanced; caustic, 88-90%, to £26. per ton; and carbonate, 90-92%, £19. 10s. to £20. per ton.

LIVERPOOL DRYSALTERIES.

THURSDAY.

Montreal potashes steadily held at 35s. 6d. to 36s. Pearl Ash nominal. Cutch in moderate demand. Gum arabic firm. Logwood and fustic steady. Castor oil quiet, at 3½d. for good seconds Calcutta, 3⅝d. for first pressure French, 3¾d. for second pressure French, and 3¾d. per lb. for Calcutta shipment on to January next. Gambier: Block, 18s. 0d. to 19s. on spot; 18s. to 18s. 1½d. for June-July; 17s. 10½d. for July-August; and 18s. for August-September shipments. Cubes, 28s. 6d. to 29s. on spot, and 27s. 9d. for August-September

Digitized by Google

Shellac steady, at 170s. to 175s. for fair T.N. orange on spot. American powdered starch, 10s. 6d. on spot, and 10s. c.i.f., for shipment; pearl, 10s. on spot, and 9s. 6d. c.i.f., for shipment. Glucose: American liquid, 43°/₀, 12s. on spot, and 9s. 9d. c.i.f., for shipment. Cream of tartar, 98°/₀ foreign powder, 80s. 6d. to 81s.; 95°/₀, 79s. Tartaric acid, English, 11½d. on spot; foreign, 10⅝d. to 11d. Citric acid: English, 1s. 10½d. on spot; foreign, 1s. 10¼d.

LIVERPOOL OIL AND COLOUR MARKET.

THURSDAY.

OILS.—Palm oil quiet, with Benin quoted at £27. 7s. 6d. per ton; hard oils, £26. 17s. 6d.; soft oils, £27. 12s. 6d. Cottonseed oil steady, at 29s. 6d. to 31s. per cwt. for Liverpool refined in export barrels. Linsed oil firm, at 25s. 3d. to 25s. 6d. for Liverpool makes in export casks. Tallow quiet at 33s. 6d. to 33s. 3d. per cwt. c.i.f., for South American beef. Rosin quiet. Turpentine steady at 30s. 9d. per cwt. on spot. Petroleum quiet at 0½d. for Russian and Roumanian, and 7d. to 8d. for American refined oils. Petroleum spirit steady, at 1s. 0½d. to 1s. 3d. per gallon.

COLOURS.—Red lead, English, £21. 10s.; white, £22. 10s. to £22. 15s.; emerald green, 1s. per lb.; Brunswick green, 10s. to 45s. per ton; Venetian red, lump, 7s. 6d.; powder 5s. to 6s. 6d. per cwt.; vermilion, English, 2s. 4d.; China, 3s. per lb.; Prussian blue, 1s. 10d. to 2s. 6d.; Brunswick, 28s. to 34s. per cwt.

HULL PAINT, OIL, AND COLOUR REPORT.

THURSDAY.

OILS.—Linseed oil has continued a firm and dearer market, having advanced during the week from 10s. to 15s. per ton. Refined cotton oil has been slack and reduced in value by about the same amount. Evidently the soap makers do not anticipate much rise in the price of materials, or they would hardly reduce prices of soap, although naturally prices will come lower when the new seed comes upon the market in October. Amongst the principal imports here to date, as against the same period a year ago, are:—Wheat 2,848,205 qrs., against 2,805,637 qrs.; flour 150,477 cwts., against 259,810 cwts.; linseed 501,481 qrs., against 308,780 qrs.; rapeseed 71,157 qrs., against 60,929 qrs.; cottonseed, Egyptian, 127,908 tons, against 111,443 tons; other kinds 127,908 tons, against 102,219 tons; oilcake 18,167 tons, against 29,012 tons; hemp 93,237 cwts., against 117,110 cwts.; olive oil 3,490 tuns, against 2,951 tuns; tar 6,073 brls., against 8,960 brls. Amongst the weekly imports are 20,627 qrs. linseed, 4,214 qrs. rapeseed, 3,174 tons cottonseed, 4,564 cwts. margarine, 22,209 cwts. sugar, 169 tons oilcake, 2,914 pkgs. colours, 1,648 cwts. hides, 84,208 lbs. wool. Exports: Oil 10,016 cwts., colours 2,987 pkgs. chemicals 2,219 pkgs. Linseed oil firm, naked spot 22s. 10½d. to 23s.; September-December, 22s. 9d. to 22s. 10½d.; January-April, 23s. 3d. paid; boiled and refined, £1. to £1. 10s. per ton extra. Exports during the week: 2 tons America, 11 Germany, 4 Norway, total 17 tons. For linseed the market has been dearer, La Plata spot, 43s. 6d.; September-October sold at 44s. 3d.; December-January, 42s. 3d.; January-February, 42s. Refined cotton oil, 26s. 6d. spot naked; September-October, 20s. to 20s. 3d.; November-April, 23s. 3d.; casks £. and barrels £1. 7s. 6d. per ton extra. Exports during the week: 57 tons Germany, 14 Holland, 1 Norway, 4 Sweden, total 76 tons. Cottonseed steady on passage and spot £8. buyers, October sold at £7. 6s. 3d.; November-January, £7. 1s. 3d.; January sold at £7. 2s. 6d. Bombay, September-October, £5. 18s. Turpentine lower, spot 30s. 6d.; October-December, 40s. 1½d.; January-April, 41s. 9d. Rosins unchanged from 10s. 9d. Olive oil, Levant, from £40. to £42. per tun. Cakes: linseed cakes, improving demand makes a firmer market, being generally 5s. per ton higher; cotton cakes quite unchanged; rape cakes none.

TYNE CHEMICAL REPORT.

THURSDAY.

The chemical market continues steady with a fair demand, caustic soda, 70°/₀, £9. 15s.; and 76-77°/₀, £10. 10s. per ton. Bleaching powder quiet, at £4. 15s. to £5. 5s. per ton. Soda crystals locally firm, at £2. 17s. 6d. to £3. 2s. 6d. per ton gross weights. Sulphur steady at £5. to £5. 5s. per ton.

Bleaching powder, softs, £5. 5s. per ton, nett; do., hards, £5. 10s. per ton, nett; caustic soda, 76-77°/₀, £10. 10s. per ton, nett; do., 70°/₀, £9. 15s. per ton, nett; recovered sulphur, 2 cwt. bags, £5. 5s. per ton, nett; alkali, 30°/₀, £4. 17s. 6d. per ton, nett; do., 36°/₀, £5. 2s. 6d. per ton, nett; do., 40°/₀, £5. 7s. 6d. per ton, nett; hyposulphite of soda, 5/7 cwt. casks, £6. 5s. per ton, nett; do., 1 cwt. kegs, £7. per ton, nett; silicate of soda, 75° Tw., £3. 10s. per ton, nett; do., 100° Tw., £3. 17s. 6d. per ton, nett; do., 140° Tw., £4. 7s. 6d. per ton, nett; soda crystals, casks, £3. 2s. 6d. per ton, gross weight; do., 2 cwt. bags, £3. 2s. 6d. per ton, nett; sulphate of soda (saltcake), £2. 2s. 6d. per ton, nett; pearl hardening, £3. per ton, nett; pure white sulphate of alumina, £4. per ton, nett; blanc fixe, £6. per ton, nett; chloride of barium, refined crystals, £7. 10s. per ton, nett; do., crude calcined, £7. 5s. per ton, nett; sulphide of sodium crystals, £5. 15s. per ton, nett; do., refined concentrated solid, 60-62°/₀, £8. per ton, nett; carbonate of alumina, £29. 10s. per ton, nett; aluminate of soda, £30. per ton, nett; hydrate of barium, fused, 50-60°/₀, £13. per ton, nett; do., crystals, 45-48°/₀, £12. per ton, nett; strontium hydrate crystals, 90-95°/₀, £8. 10s. per ton, nett; do., carbonate, 90-95°/₀, £10. 15s. per ton, nett.

COALS.—Market continues very steady, with a good demand for all best quality coals. For current shipment, prices are:—Best Northumbrian steam coals, 16s. to 16s. 3d. per ton; second quality, 15s. to 15s. 3d. per ton; small steam coals, 10s. to 11s. per ton; best gas coals, 15s. 6d. to 16s. per ton; Durham bunkers, 14s. to 14s. 6d. per ton; coking coals, 14s. 6d.; household coals, 16s. to 17s. 6d. per ton; foundry coke, 25s. per ton; gas coke, 20s. per ton.

WEST OF SCOTLAND CHEMICALS.

GLASGOW, THURSDAY.

The Scottish calico printers are very quiet, and therefore making but small calls for supplies of the colour chemicals used. Printing orders would come through in a fair enough volume, but the deterrent is the dearth of sufficiently cheap cotton. The dyeworks of the country are also on the quiet side, partly from the same cause. Although there is no great movement in drysalteries, late price figures are well maintained, and this is the case also with most of the chemicals, sulphate of copper being the only prominent exception. The heavy chemicals are in fair demand, with recent figures unaltered, although the further advance in fuel causes makers to turn their thoughts to a rise. Sulphate of ammonia continues steadier than is its wont, and the position to-day is about the same as during the past three weeks. Mineral oils and paraffins are all unchanged and healthy of movement. The makers are now about fully contracted forward in burning oil.

Chief prices current are:—Alum (in lump), £5. 5s. to £6., nett, ex quay, Glasgow; bicarbonate of soda, 5-cwt. casks, £6. 7s. 6d.; and 1-cwt. casks, £6. 15s., nett, Liverpool; bichromate of potash (home-make), 3½d., less 2½°/₀ for Scotch and English deliveries (for export, 3¼d. nett, f.o.b. Glasgow); bichromate of soda (home-make), 3d., less 2½°/₀ for Scotch and English deliveries (for export, 2¾d. nett, f.o.b. Glasgow); bleaching powder, 35-37°, £4. 12s. 6d. to £4. 17s. 6d., nett, Tyne; borax, English refined, £16., and boracic acid, £25., nett, Glasgow; caustic soda, white, 76°, £10. 10s.; 70-72°, £9. 15s.; 60-62°, £8. 15s.; and cream, 60-62°, £8. 15s., all nett, Liverpool; chlorate of potash, 3¾d., nett, Glasgow; creosote (ordinary coal-tar and blast-furnace), 2¼d., naked, f.a.s. Glasgow; nitrate of soda, 11s. 1½d.; paraffin scale, hard, 2d. to 2¼d.; and soft, 2⅜d. to 2½d. per lb.; paraffin wax, 120° semi-refined, 3d. to 3½d.; paraffin spirit (naphtha), 10d. to 11d. per gallon; paraffin oil (burning), special quality, 6¾d.; ordinary sorts, 6½d. and 6¼d. (new season's contract prices), at Glasgow and other big centres; ditto (lubricating), 865°, £5. 12s. 6d. to £5. 17s. 6d.; 885°, £6. 7s. 6d. to £7. 7s. 6d.; 890-895°, £7. 2s. 6d. to £8. 2s. 6d.; prussiate of potash, 6d., nett, f.a.s. Glasgow; salammoniac, first and second white, £42. and £40., less 2½°/₀ any port; saltcake, 40s.; soda ash, £5. 10s. to £5. 15s., nett, Tyne; soda crystals, £3. to £3. 2s. 6d.; sulphate of ammonia, £12. to £12. 1s. 3d., prompt f.o.b. Leith; sulphate of copper, £26. 17s. 6d., to £26., less 5°/₀ Liverpool, prompt.

New Companies.

Bovey Lignite Co., Ltd.—Capital £900., in 800 ordinary shares of £1. each, and 800 deferred shares of 2s. 6d. each. This company has been formed to acquire lands, mines, quarries, etc., in Devon or elsewhere, and to win, manipulate and prepare for market lignite, clay, ores, metals and minerals. No initial public issue. The first directors are R. B. Phillpotts, M. M. Olsson and R. J. Woods; qualification £100.

Digitized by Google

Earogen Ltd.—Capital £35,000, in £1 shares. This company has been formed to acquire certain patents and patent rights relating to the generation of steam and other fluid pressure for motive power, and to apparatus therefor, and to carry on the business of manufacturers of and dealers in chemical and other substances, liquids and apparatus, etc. No initial public issue. The first directors are E. M. Touzeau, A. C. Jarvis and G. G. Belcher; qualification (except first directors) £100.; remuneration (except managing director) £50. each per annum (£25. extra for chairman) and 5% of the surplus profits available for distribution after providing for 10% dividend and for any reserve or suspense fund, divided.

Conrad Wm. Schmidt (F. A. Glaeser), Ltd.—Capital £100,000., in £1. shares (60,000 5% cumulative preference and 40,000 ordinary). This company has been formed to acquire the business carried on at Stratford by F. A. Glaeser and Heinrich Schmidt (as administrator of the estate of the late Conrad Wm. Schmidt (F. A. Glaeser), and to carry on the business of varnish, japan, enamel, colour, oil and dye manufacturers and dealers, etc. No initial public issue. There are to be 10,000 "management shares," which shall not be of any denomination, and shall not entitle the holders to any interest in the capital of the company, nor confer any right to attend or vote at general meetings. These shares are to be distributed among such of the employes as the directors think fit, but no money consideration is to be taken for the same. Each such share, whilst held by any employe, is to rank for dividend as though it were a fully paid £1. ordinary share. The first directors are F. A. Glaeser and H. Schmidt (both permanent); qualification £500. ordinary shares or stock; remuneration of any director not holding any office of profit under the company, £250. per annum. F. A. Glaeser is managing director.

J. B. Jenkins and Co., Ltd.—Capital £7,500. in 250 5% cumulative preference shares of £10. each, and 5,000 ordinary shares of £1. each. This company has been formed to take over the business of silica brick manufacturers, carried on at Neath as J. B. Jenkins and Co. Minimum cash subscription £3,000. The first directors are I. Butler, J. John and L. Jenkins; qualification £250.; remuneration as fixed by the company.

Kali Selogiri Syndicate, Ltd.—Capital £25,000., in £1. shares. This company has been formed to adopt an agreement with R. C. Wright and L. A. van den Bergh van Heinenoord (vendors), to cultivate and exploit the Kali Selogiri Estate in Java, and to carry on the business of planters of india-rubber, gutta percha, balata and other gums, coffee, tea, cocoa and other produce, etc. Minimum cash subscription 10,000 shares. Purchase consideration £14,250 (£4,000 shares and balance cash). The first directors are R. C. Wright, W. Taylor and H. de Courcy Hamilton; remuneration £50. per annum, divided. Registered office, Leadenhall House, 101, Leadenhall-street, E.C.

Pavitt and Co., Ltd. Capital £2,000., in £1. shares (1,000 preference and 1,000 deferred). This company has been formed to carry on the business of candle, perfume and soap manufacturers and merchants, stationers, chemists, etc. No initial public issue. The first directors are A. V. Cowell (chairman) and G. P. Marshall, and not more than two others to be appointed by them within six months; qualification 100 shares.

NOTICE.

On and after Monday next, the 23rd inst., our Manchester address will be

Barton House,
66, Deansgate.

LATE ADVERTISEMENT.

CHEMIST, young, 5 years oil and colour works, University training, desires position as Chemist or Assistant Manager. Box "1,505," *Chemical Trade Journal* Office, 265, Strand, London, W.C.

Notices.

All communications for the *Chemical Trade Journal* should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, Strand, LONDON, W.C.

Our Registered Telegraphic Addresses are:—

"Trepex, London."
"Expert, Manchester."

Our Telephone Numbers are:—

London: 13692, Central.
Manchester: 3060.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal*—payable in advance—including postage to any part of the world, are as follows:—

Yearly (52 numbers) ..... **12s. 6d.**
Half-Yearly (26 numbers) ..... **6s. 6d.**
Quarterly (13 numbers) ..... **3s. 6d.**

Advertisements.

Prepaid Advertisements of Situations Vacant, Premises on Sale or To Be Let, Miscellaneous Wants, and Specific Articles for Sale by Private Contract are inserted in the *Chemical Trade Journal* at the following rates:—

30 Words and under ..... 2s. 6d. per insertion.
Each additional 6 words ..... 0s. 6d. ,,

Advertisements of Situations Wanted are inserted at the following rates when cash is sent with order:—

24 Words and under ..... 1s. 0d. per insertion.
Each additional 6 words ..... 0s. 3d. ,,

Advertisers would oblige by writing advertisements and letters of instructions on separate sheets of paper.

Trade Advertisements, Announcements in the Directory Columns, and all Advertisements not prepaid, are charged at the Tariff Rates, which will be forwarded on application.

CURRENT TOPICS.

THE RAILWAY PROBLEM.

THE position of British railways and the problem of their future working was the subject chosen by Lord Brassey for his Presidential Address at the Autumnal Meeting of the Association of Chambers of Commerce, held at Liverpool on Wednesday last. The pending labour dispute in the railway world has focussed public attention on this question, and other considerations which are familiar to our readers have recently caused railway matters to be much discussed amongst manufacturers and traders generally. It was therefore opportune that the President of such an influential commercial organisation, representing no fewer than a hundred Chambers of Commerce, should select this subject for consideration.

Lord Brassey's address raised several points which will doubtless be debated very seriously in the near future. In his opening passages he alluded to the fact that the latest trade statistics established a record; that while British imports had increased from fifty-nine millions in 1904 to sixty and a half millions in 1906, the exports increased in the same period from eighty-five millions to a hundred and three millions. These imposing figures respecting the movements of trade naturally lead up to the discussion of measures which, as Lord Brassey pointed out, will at no distant date call for consideration. He referred first to the deliberations of the Royal Commission on Canals and Waterways, observing that the inquiry has been wide and exhaustive. Many witnesses have been examined, the Commissioners have visited Ireland and Scotland, and they have made an important tour through France, Belgium, and Germany. The policy of foreign Governments has been studied, and the impression apparently received by the Commissioners is that on the Continent public money has been spent with an unstinting hand on canals or the canalisation of rivers. The results of this expenditure, said Lord Brassey, have been beneficial to trade and commerce; traffic is free of tolls, and on many routes the volume is enormous. In this country, on the other hand, the conditions are not identical, yet even with us the time may come (he added) when it may be deemed advantageous that some portion of the bulky and less valuable goods now carried on the railways should be handed over to canals along the main routes, adapted for navigation by barges of adequate size, and propelled, necessarily at slow speed, by mechanical means.

This brought Lord Brassey to the consideration of the present position of British railways. He observed that throughout the inquiry by the Royal Commission on Canals the railways have been under review. The managers of the leading lines appeared as witnesses, and they tendered a large body of evidence; as might have been expected, railway men are not favourable to canals. Meanwhile, said

Digitized by Google

Lord Brassey, the trader complains. He compares rates on British railways with the charges in Continental countries. It is true that the great advantages which British traders enjoy in respect to prompt delivery are not perhaps sufficiently appreciated; the fact is overlooked that while it is possible to carry goods for long distances at a low cost per ton per mile, it is impossible to carry the same goods at such a low rate for short distances. But these considerations notwithstanding, the President of the Associated Chambers of Commerce admits that in railway management in England competition is carried on to excess. An immense capital is wasted on duplicate lines not called for by the public. The traders and the railway workers complain: the latter say that their wages are too low and their hours too long; while the trader brings the charge that the traffic rates and charges are excessive.

This conclusion, enunciated by the President of such an influential commercial body, may quite conceivably have a marked effect on the future of our railway system. Any Royal Commission appointed by Parliament to consider this problem will be compelled to give great weight to the representations made by such commercial experts as the Council of the Associated Chambers of Commerce, and here Lord Brassey threw out the significant hint that, in his opinion, some measure of State ownership would be the outcome of any such inquiry. He said that if we in this country were taking a new departure to-day, there could hardly be a question as to what Parliament would do. British railway administration, he observed, is honest, able, and actuated by a keen desire to serve the public good—and with this declaration we hardly think that any serious commercial man will quarrel. But in his summing up of the situation Lord Brassey went on to emphasise the fact that the railway companies are hard pressed; that it is difficult to maintain dividends, not excessive in amount; that competition is severe between rival systems; and that we are probably on the eve of a change of policy. In Germany, in Russia, in Belgium, and more recently in Italy, the railways have become the property of the State, the requirements of the public are fully considered, and the results to the Exchequer have been satisfactory.

Having hinted at what, in his opinion, appeared to be the only satisfactory solution of the railway problem, Lord Brassey went on to point out that it is difficult to change a policy to which we in this country have so long adhered. The capital value of British railways may be taken roughly at twice the amount of the National Debt, and to deal equitably with interests so vast would be an operation which would heavily tax even British financial resources. Lord Brassey suggests that State ownership might possibly begin in Ireland, where the financial operation would be on a limited scale. He considers that the savings resulting from unity of management would certainly allow of considerable reductions in rates and tolls. As to administration, he sees no reason to apprehend failure; the postal service, the dockyards, and the Civil Service are highly efficient.

It is clear that Lord Brassey looks with considerable favour on some measure of State ownership, but, as he pertinently points out, the difficulties in the way are enormous. It would appear open to question whether Ireland is a favourable field for such an experiment, since the conditions are far from parallel, and the railway problem is certainly not most acute in that country; but that some wise and far-reaching solution of such a grave problem must at no distant date be reached is not open to question. Cheap and efficient transport is a vital consideration for every industry, and though there is no doubt whatever that the British Government will not embark on any rash or hazardous experiments with the railway system, there is also no doubt whatever that the solution of the problem cannot long be delayed. In the meantime, manufacturers and traders generally will view with concern the development of the labour trouble on the railways, and it is to be hoped that counsels of conciliation will prevail, and that the dislocation of trade which would inevitably result from a general strike of railwaymen will be avoided. As to the solution of the railway problem as a whole, the subject is of national importance, and it should be approached in that spirit of detachment from petty side issues which, more than any other quality, is seldom absent from British statesmanship.

CONSULAR COUNSEL.

The value, or otherwise, to commercial men, of the sheaf of Consular Reports which annually finds its way from the Government printers has been discussed so frequently that we do not propose seriously to reopen the question, but the recommendations to British traders which are included in almost every important report call for passing attention. From the notes on "Trade Openings in Belgium," to be found in Consul-General Hertslet's annual report on Belgian trade, it does not appear that there are many openings for British chemicals in that country, but it is interesting to note his general hints to British traders, though these are by no means new. Consul-General Hertslet considers it practically impossible for a Consular Officer to give general advice to British firms with regard to the best way for them to further their business with the foreign country or town in which he (the Consul) may be stationed. Most individual business houses and traders, he observes, have a separate way of carrying on their affairs, and advice which is given to one person is resented by another, who conducts his business in a different manner. He therefore does not offer advice collectively to British manufacturers and merchants, and in this he is no doubt wise. The Consul refers to the practice of some British firms of obtaining, through the Intelligence Branch of the Board of Trade, or through a Consul, the names of likely buyers of their goods, with whom they communicate, and (he adds) in many cases they thus establish a fair trade. Only in exceptional cases, however, is it taken into consideration that the foreign taste in regard to certain articles is not necessarily the same as the British. For firms in a fairly large way of business there is no better way of making their goods known than by sending travellers to open up the market. British firms, says the Consul, must be prepared to meet the particular inclination of the foreign buyer, and he goes on to emphasise the fact that it is in this way that German firms obtain so large a share of Continental trade. He specially deprecates the idea of "educating the foreigner to British tastes."

In commenting on the fact that comparatively few business men study Consular reports, a writer in the *Glasgow Herald* recently expressed wonder as to what basis many of these same business men have for their complaints that the British Government give too little attention to commercial interests. As a matter of fact, the writer continued, there is not a report issued by the Board of Trade, the Foreign Office, or the Colonial Office, that does not contain the most valuable information on the commerce of the district dealt with. Curiously enough, however, each of these reports bears witness to the lack of

Digitized by Google

enterprise or the deliberate outraging of local susceptibilities by British traders. Then follows the familiar instance of a firm sending out to China packages bearing phrases and colours that were absolutely anathema to the mass of the Celestial population.

In the last report of our British Consular representative on the trade of Chinkiang, another and more recent example of short-sighted policy is quoted. The Consul observes in reporting this incident that British firms who are practically interested in the development of China, and whose lines of business demand a special expert knowledge, would do well to keep in touch with an agent or representative possessing the requisite special knowledge, who should be resident at one of the four centres of trade in China—Hong Kong, Shanghai, Tientsin, or Hankow—and who could take up the firm's interests on the spot at short notice. A case recently occurred in which this Consulate had interested leading Chinese in a scheme calculated to develop a portion of the locality and involving the employment of a certain class of machinery. Application was made by the Consulate to the Board of Trade, which notified the British firms interested. All the firms but one contented themselves with despatching catalogues and price lists to Chinkiang; the exception also notified its agent in Shanghai, and he—a Japanese gentleman—paid a special visit to Chinkiang to make inquiries on the spot. After inspecting catalogues, however, the Chinese preferred the goods of another British firm, but required expert explanation; and, after telegraphing to England this Consulate was able to locate the selected firm's correspondent in China—six months after the firm in question had been notified by the Board of Trade of the Chinkiang inquiries!

The Consul adds that a Japanese agent in China is better than none at all, but he adds that the imitative Japanese agent will probably be an ultimate competitor.

INDIAN TRADE IN 1906.

We have already pointed out in these columns the desirability, from the point of view of the chemical manufacturer, of cultivating the Indian trade in chemicals, and in view of the importance of this subject we give below some interesting notes from our Indian correspondent on the trade of the great dependency in 1906. The official Indian year ends in March, and the available figures are of interest.

The importations of merchandise into India during the year under review amounted to Rs.1,083,069,144., as against Rs.1,030,656,602 in the previous year, or an advance of 5%, and the exports of Indian merchandise were valued at Rs.1,730,704,827. as against Rs.1,581,791,642. in 1905, or an increase of 9⅖%.

The importations were from the following countries, in the proportions indicated:—United Kingdom 66⅔%, Germany 5 3/10, Belgium 4, Austria-Hungary 2⅘, Java 2 7/10, Straits Settlements 2⅗, United States 2 3/10, Mauritius 2, Japan 1½, China 1⅖, France 1⅖, Italy 1%. The exports of Indian merchandise were distributed as follows:—United Kingdom 26 9/10%, China 10 3/10, Germany 11, United States 9, Japan 4 1/10, France 6⅘, Belgium 4 1/10, Straits Settlements 3⅘, Ceylon 3 7/10, Italy 3 3/10, Austria-Hungary 3 3/10, Egypt 2⅗%.

Among the imports into India, with their values, were:—Mineral oil, Rs.24,269,000.; copper, Rs.13,931,000.; instruments and scientific apparatus, Rs.11,987,000.; drugs, Rs.7,801,000.; aniline and alizarine dyes, Rs.7,493,000.; chemicals, Rs.6,876,000.; salt, Rs.6,676,000.; matches, Rs.6,313,000.; colours and paints, Rs.5,675,000; earthenware, Rs.3,899,824.; soap, Rs.3,228,156.

Of the total imports of chemicals, bleaching materials represented Rs.339,000; calcium carbide, Rs.113,000; cyanide of potassium, Rs.292,000; disinfectants, Rs.275,000; caustic soda, Rs.703,000; bicarbonate of soda, Rs.428,000; soda (other sorts), Rs.118,000, etc. The year on the whole was notably one of high values in the chemical and drug trades. Drugs were imported to a value of 15⅗% over 1905, which is the largest recorded yearly increase. The remarkable development of the rise in camphor is shown by the fact that whilst the value of the imports was Rs.2,296,000., or an increase of 71¼% over the previous year, the quantity imported was less by 21%. The specific value of imported camphor rose by 16% in 1904, 37% in 1905, and 42% in 1906. At present camphor stands at the highest figure known in thirty years. The quinine trade has been very dull; the lowest price on record being reached. The imports of aniline and alizarine dyes improved from 11,605,784 lbs. to 11,784,144lbs., but the value declined from Rs.7,571,000. to Rs.7,493,000. These figures represent a rise of 1½% in quantity and a fall of 1% in value, the average price per lb. having declined from 10 5/12 annas to 10⅙ annas, or 2½% lower. Bombay continues to be the principal port for dyes, taking about 76%. Imports of aniline increased from 5,308,207 lbs., valued at Rs.4,371,000., to 6,054,249 lbs., and Rs.4,655,000; of alizarine the imports decreased from 6,297,577 lbs., valued at Rs.3,200,000., to 5,732,893 lbs. and Rs.2,838,000. The total value of mineral oils imported represented 8½% more than 1905; of this,80% was kerosene.

There was an increase in the imports, of matches, especially from Japan, which rose to Rs.145,000. Efforts are being made to create an Indian match industry. The imports of soap continue to grow, as likewise colours and paints.

As regards the exports of Indian merchandise, lac was exported to the value of Rs.34,997,740, as against Rs.31,801,161. in 1905; indigo, Rs.7,004,773., as against Rs.5,863,770 in the previous year. Chemicals, drugs, narcotics, and dyeing and tanning materials aggregated Rs.115,489,000., as against Rs.114,484,000., animal bones, Rs.5,520,241. against Rs.4,978,770., horns, Rs.1,691,552., against Rs.1,749,944.; stick and seed lac, Rs.1,286,2424. against Rs.779,613.; mica, Rs.3,824,988., against Rs.2,394,413.; oil cake, manure, etc., Rs.7,599,121., against Rs.6,898,380. Indian metals, manganese ore, etc., Rs.9,149,578. Shellac and button lac, Rs.33,420,265.

The exports of saltpetre increased from 336,429 cwts., valued at Rs.3,850,000., to 353,378 and Rs.4,140,000., whilst borax represented 5,613 cwts., valued at Rs.115,300. As regards indigo, the absolute necessity for standardisation of strength in the product is recognised.

Increased orders for indigo were received from Persia and Japan. The total exported was 35,102 cwts. (against 31,186 cwts. in 1905), of which the United Kingdom took 7,942 cwts., the Continent of Europe 7,063 cwts., Egypt 9,195 cwts., United States 1,258 cwts., Japan 1,600 cwts., and Persia 2,422 cwts. Paraffin wax was shipped to the value of Rs.1,243,000 or 60,209 cwts., and the exports of candles produced from petroleum amounted to 5,095,000 lbs., valued at Rs.1,421,000, or a decline of 15⅕%. The exports of mica have increased 59¾%, and the advance in stick-lac is striking, being an increase of 188% in 1904, 52⅘ in 1905, and 126% in 1906, whilst the specific value rose in those years 5¾%, 9¾%, and 36 7/10% respectively. Lac has risen on account of the electrical activity and the increased demand for high-class varnishes in India. Shellac

Digitized by Google

represented 205,461 cwts., and button lac 37,117 cwts. For purposes of exchange, the rupee may be taken at 1s. 4d., and the anna at a penny. Thus, Rs.15.0 equal £1.

NITRATE OF SODA.

The market remains stagnant, but is nominally firm, in the absence of arrivals at ports of call. While consumers take no interest in the article either on the spot or for spring delivery, in speculative circles some business is reported in cargoes as far forward as 1910; the buyers are enterprising, considering the high prices asked by sellers, and the uncertainty as to freights—these latter are not likely to remain at the present low level when the coal "boom" peters out. Nitrate for prompt shipment has sold in Chili down to 8s. 10½d. per quintal, f.o.b., while 9s. 0¾d. is said to have been paid on this side, a somewhat curious circumstance, seeing that all the large importers have their own houses or representatives in Valparaiso and Iquique. Out of 119,000 tons loading for Europe on the 1st inst., only 30,400 tons had cleared up to the 15th, and it is estimated that the month's total will not exceed 75,250 tons. The national holiday in Chili will as usual interfere with work, both at ports and on the "pampa," but 98,000 tons were shipped to Europe in September, 1902, when there were only 340,000 tons of nitrate of soda on the West Coast, whereas the stocks now amount to 560,000 tons; two new shipping ports have since then come into existence, and the selling price was 6s. 4½d. per quintal!

GERMAN CHEMICALS.

The Uerdingen Chemical Works (vormals Weiler ter Meer) are issuing at 130 £50,000. new shares, in order to extend their plant, at present unable to cope with the business offering. The Harburg-Stassfurt Company pays 15% dividend, against 12% last year, and the Concordia Chemical Factories of Leopoldshall 15% on £105,000. capital, against 16% on £60,000. and 8% on £45,000. There are as yet few visible signs of a set-back in Germany's typically prosperous trade.

A meeting of the Potash Syndicate was arranged to take place in Berlin yesterday (Friday) to consider the terms of admission of new members. A serious inrush of water has caused a cessation of work at the mines of the Heldrungen Company, the occurrence, by no means an isolated one, causing some consternation in potash circles.

The Rhenish Steel Works of Duisburg, in the year to June 30, produced 2,492 tons of sulphate of ammonia, against 1,683 tons in the preceding twelvemonth; the output of refined tar was 873 tons, of raw tar 416 tons, and of benzol 408 tons, compared with 768, 2,401, and 509 tons respectively in 1905–6. The Company made a net profit of £238,870., and increases its dividend from 12 to 18%.

THE LABOUR MARKET.—A Memorandum that has been prepared by the Labour Department of the Board of Trade for the *Board of Trade Labour Gazette*, states that employment in August showed on the whole some decline as compared with July. The decline was most marked in the case of shipbuilding, but there was also some falling off in the engineering trades, and a seasonal decline in the printing trades. On the other hand there was a slight improvement in the building trades. As compared with a year ago there was an improvement in all the principal industries except engineering, shipbuilding, printing and bookbinding, in each of which there was some decline. There was a net weekly rise in wages during August of £48,200. per week, which was mainly accounted for by advances to coal miners. In the 273 trade unions, with an aggregate membership of 632,068 workpeople, making returns, 25,458 (or 4.0%) were reported as unemployed at the end of August, 1907, compared with 3.7% at the end of July, 1907, and 3.8% at the end of August, 1906.

CHEMICALS, ETC., IN JAPAN.

FROM the annual report of the British Consul-General on Japanese trade in 1906, it appears that the total import and export trade of Japan during the year amounted to £86,009,190., an increase over the sum for 1905 (£82,694,811.) of £3,314,379., or just above 4%. There was at the same time a very great change in the balance of trade, as shown in the accompanying table:—

Year.	Imports.	Exports.	Total.	Difference between imports and exports.
	£	£	£	£
1906..	42,750,878	43,258,312	86,009,190	– 507,434
1905..	49,871,589	32,823,222	82,694,811	+ 17,048,367
1904..	37,962,576	32,591,216	70,493,792	+ 5,311,360
1903..	32,374,250	29,553,374	61,927,624	+ 2,820,876

The course of trade during 1906 was generally held to be favourable to Japan. For the first time since 1895 the exports exceeded the imports, and though the customs returns take no notice of "invisible imports and exports," the condition of affairs was regarded as facilitating the retention of specie in the country and the expansion of industries. The increased export trade was looked on as an indication of Japanese industrial expansion, and the result of the year's trade was considered encouraging. The money market was easy, there being a boom in everything, especially towards the end of the year.

The decline in imports for 1906 was 14.3%. This decrease was due principally to the restricted demand for some commodities after the conclusion of the war, and also to the large stocks carried over from 1905. The year has ended with favourable prospects of continued demand. The new tariff which came into force on October 1 seemed to make but little difference in the volume of imports. There were no exceptionally heavy entries in anticipation of the new duties—March, April and May showing the largest totals, while though the imports for the whole year declined over £7,000,000. the imports for the last three months were only £102,144. less than the total for the corresponding months in 1905.

The following figures show the imports of chemicals, etc.:—Carbolic acid, £20,119.; alcohol, £18,795.; glycerine, £16,128.; resin, £29,320.; shellac, £14,952.; bicarbonate of soda, £17,924. The most important imports under the heading of "Dyes, colours and paints" were aniline dyes and artificial indigo, which between them accounted for over 65% of the total import of £990,347. Other items were lacquer £32,657., varnish £20,326., alizarine dyes £13,249., vermilion £13,224., and logwood extract £12,930.

The imports under the heading of "Oil and Wax" increased slightly in 1906; the increase was, however, still smaller when compared with the average for 1901-05. Most of the items showed advances, those not included in the annex being principally castor oil (£10,321.), linseed oil (£50,133.), stearine (£22,146.) and mineral colza, while candles, cocoanut oil and olive oil all showed small decreases. The import of kerosene oil was nearly stationary, and indeed showed a decline both on the year 1904 and the average for 1901-05. Though there is a constantly increasing consumption of kerosene this is met by the increased production of the home wells, while the heavy import duty also tends to diminish the import. The Japanese oil production is increasing steadily, some 4,300,000 cases having been produced in 1906 compared with 2,760,000 cases in 1905. Proposals are being made for the import of crude oil (thus avoiding the high duties on refined oil) and the establishment of refineries in the country. Of the oil imported in 1906, 44,510,539 gallons came in cases, while 14,918,469 gallons were tank oil.

The exports of Japan during 1906 advanced to £43,258,312. from £32,823,222. in the previous year, an increase of £10,435,090 or 31.8 per cent. This advance was made up of increases in all the sections of the export trade with the single exception of tobacco; the major part of the advance, however, was contributed by increases of over £4,500,000. in silk, over £1,000,000. in metals, nearly £1,000,000. in beverages and comestibles, over £800,000. in cotton and other tissues, and over £2,000,000. in the miscellaneous section.

INDUSTRIAL POISONING.*

(*Continued from p. 217*).

MIDLAND DIVISION.

THE Superintending Inspector for the Midland Division observes that the figures of industrial poisoning in his district are disquietening. The divisional table shows an increase from 216 cases in 1905 to 285 in 1906. The cases of poisoning by arsenic numbered 3, anthrax 2, and lead poisoning no less than 280.

Arsenic Poisoning.—Some severe cases of much interest developed in North Staffordshire, and were investigated by Mr. Walmsley and Mr. H. R. Rogers. Three men suddenly developed signs of acute poisoning. The men were engaged in recovering copper from a solution containing copper sulphate (by an electrolytic process), when they suddenly became very ill. There was some doubt whether the illness was due to poisoning by copper, lead, or arsenic, though the last seemed most probable. Experiments showed that the copper sulphate solution contained arsenic compounds, and on treating the liquid in a laboratory in exactly the same manner as it had been treated in the factory, it was found that arseniuretted hydrogen was liberated in quantities sufficient to cause the poisoning. Mr. H. R. Rogers made the laboratory test at the Newcastle High School, the laboratory having been placed at our disposal through the courtesy of the head master. Since the date of the poisoning, the method which caused it has not been used, other ways of treating the solution having been adopted which are practically harmless.

Lead Poisoning.—The subject of lead poisoning is the most unsatisfactory one that this divisional report has to deal with. The figures for the last six years show that after falling from 296 cases in 1901 to 248 in 1902, there was a rise in 1903 to 260 cases; in the figures for 1904 there was a reduction again to 229 cases, and the next year, 1905, showed a still more satisfactory reduction, namely, to 209 cases, but in the year under review the prevalence of lead poisoning is so marked that the number of cases numbered no less than 280. It will be seen, therefore, that last year's return was the highest since 1901. The trades mostly responsible for the increase are coach, motor, and perambulator making, earthenware and china making, smelting and refining, tinning and enamelling, white lead making, and miscellaneous manufactures. Mr. Walmsley (Stoke) mentions two fatal cases amongst coach painters, probably due to uncleanliness.

NORTH-EASTERN DIVISION.

Lead Poisoning.—During 1906 3 cases of lead poisoning in paint manufacture were recorded; white lead 36, 3 of which were fatal; red oxide of lead 1; and de-silvering of lead 1.

Mr. Wilson (Newcastle-on-Tyne) reports that the lead works, as in former years, contributed the majority of cases, and they arose almost exclusively in the manufacture of the carbonate. Of the 22 cases reported by one particular firm, 8 referred to men who had contracted poisoning while engaged in the stoves, an operation, when conducted on the old system, by far the most dangerous in the manufacture of white lead. The methods of filling the pans with the liquid carbonate are primitive, and unless very great care is exercised, and constant supervision maintained, the workers splash their overalls to an extraordinary extent. If these garments are not tightly buttoned up to the neck, which frequently happens, lead impregnates their ordinary clothing about the breast, and, drying with the heat of the body, gives rise to slight dust at every movement. Unfortunately these clothes are occasionally all the workers possess, and they, therefore, carry the danger with them into their own homes. The transferring of the bowls to the stove, and the stacking on shelves, all tends to splashing and spilling of the liquid with a clumsy or reckless worker. It follows, therefore, that any system by which the personal handling of the wet carbonate could be avoided is to be encouraged, and the firm having the largest proportion of poisoning cases proposes in the near future to arrange the plant so that the filling and carrying of the bowls, preparatory to stacking, will be much simplified. Further, it is proposed to turn much more of the wet carbonate directly into white lead paint, never drying it at all. It is significant, in this connection, to note that the works in this district which turns all the carbonate directly into paint (mixing it with oil) has had no case of poisoning for two years.

In certain factories it has been customary to allow women to wash the pots as they come from the whitebeds. It was observed, however, that corrosions adhered to these pots, or particles were left inside, and the women were thus exposed, in a minor degree, to lead dust. This being a contravention of Regulation 11, the firms concerned were requested to terminate the practice, and now men do this work. It has been recognised that temperate men, regular in their habits, and careful in sustaining themselves with nourishing food, are far less likley to develop plumbism than irregular living and improperly fed workers. Accordingly, every effort has been made on the part of one firm to gradually collect a staff of steady men, and although this was difficult during the years of great industrial activity on Tyneside, they have been now fairly successful. The irregular and inexperienced workers, I noticed, are very dirty in their work, and frequently present themselves for examination with lips and faces smeared with lead, and the carbonate in a caked form adhering to the moustache.

Mr. Allhusen (Newcastle) says:—Last year analysis of some samples of dust taken from the beams above the melting pots in lead works showed a quite appreciable amount of oxide therein. This year, attracted by the fumes which arise from the opening of the retorts in the distillation of the zinc from argentiferous lead, I collected some dust which had settled on the beams of the distilling room, just above the pots, and found on analysis that whereas, as was to be expected, most of the fume was caused by the oxide of zinc, yet that a quite appreciable quantity of lead was carried (as litharge, most probably) away with the zinc fumes. The sample taken showed 20% of zinc (as ZnO) and 2½% of lead (as PbO). No case of sickness has ever been reported from this part of the works, and the room is clean and well ventilated, with a lowered roof. The men, too, at the instant of uncovering, generally carry cloths in their mouths, in the manner affected by the salt decomposers, which act as tolerably efficient respirators.

Mr. Butler (Huddersfield).—The three lead poisoning cases all arose at one wire factory, where a new plant had been erected for annealing wire by passing it red hot through a shallow pan of molten lead. In passing through, a considerable portion of the lead was converted into the puce oxide, which piled up to a considerable height in the pan, and the workmen were obliged to remove it at intervals. This was done by means of shovels, and a considerable amount of dust was inhaled. A ventilating hood is now provided, the floors are kept wetted, and washing conveniences are provided. At my last visit the firm promised that they would provide an outer gutter to the pan and attach tubes to it so that the oxide would fall away into receptacles at the side automatically.

Binitro Poisoning.—Mr. Butler (Huddersfield).—The most serious kind of industrial poisoning in this district arises from the manufacture of the nitro derivatives of benzine, of which the principal forms are:—Mononitro-benzol, binitro-benzol, binitro-toluol and trinitro-toluol. During the year seven cases of poisoning have come to my knowledge, but there is reason to think that the number actually occurring was much greater.

The manufacture is carried on almost entirely in the open air, and there is very little visible dust in any of the processes.

Binitro-benzol is the product of a further nitration of mononitro-benzol (a liquid formed by a previous nitration of benzine). At one of the works the process is as follows:—The monotitro is agitated with combined sulphuric acid and nitric acid in a closed mixing machine. When nitration is complete the waste acids are run off into side cisterns, and then the material itself which has become binitro is run off hot and fuming by troughs, into a cistern of water, where it is agitated by means of a long wooden hoe in order to form pellets. The pellets are then ladled out into casks and conveyed to another cistern, where they are melted up with carbonate of soda for the purpose of neutralising any waste acids that may be left. The binitro is then syphoned off into trays where it solidifies into a cake, and when cold is broken up into small pieces by means of long handled-chisels, after which it is ready to be packed. Binitro-toluol and trinitro-toluol are made in much the same manner, the latter being a further nitration of the binitro.

Certain precautions have been taken by the firm, such as providing respirators, rubber gloves, soda and milk, washing conveniences, fortnightly inspection by a doctor, and in the toluol department a fan has been fitted for the extraction of dust and vapours. The whole manufacture is primitive, and more automatic working is a desideratum.

Carbonic oxide poisoning.—Mr. Dunolly (Stockton).—Carbonic oxide poisoning is undoubtedly prevalent, but the disablement of the workers is seldom of such a nature as to require the poisoning to be reported under the Act. The workers further appear to avoid bringing their names before the management by reporting illness caused by carbonic oxide poisoning, as

* Special Abstract of the Annual Report of the Chief Inspector of Factories for 1906.

Digitized by Google

tending to prove that they are unfit physically for the work they have to perform, but an official of one of the sick clubs in connection with blast furnace workers informed me that nearly 50 slight cases of carbonic oxide poisoning had been brought to his notice between January and August of this year.

The poisoning or "gassing" affects the workers' walk; their speech is impeded and they have difficulty in forming a sentence without frequently repeating the same word; the eyes are restless, and there is a marked tremor of the fingers when extended. I have noted some of these symptoms in a man employed as time-keeper, who had been gassed eight years previously, whilst employed at a blast furnace. Gassing also occurs among men working about internal combustion engines driven by gas from the blast furnaces or from gas producers. Such engines are frequently provided with inspection pits, sunk below the ground level, where any escape of gas from leaky joints accumulates, to the danger of the men engaged in repairs. Producer gas plants have been found erected in small unventilated rooms, no instructions or appliances being provided for dealing with cases of asphyxia. Where these defects have been found the occupiers have been instructed to take the necessary precautions.

Blast furnace gas is now much used for power purposes, by feeding it directly to internal combustion engines, instead of burning the gas, as hitherto, in steam boilers. This development appears to be gaining some favour owing to the increased reliability of such gas engines, due to recent improvements. It may offer greater danger of gassing, but both the workers and the general public have the undoubted advantage of the elimination of all dust from the gas before it can be introduced into the gas engine. In a gas-fired steam boiler the gas enters the furnace in its impure condition at some pressure, and the dust is then thrown into the air by the boiler chimney. But when used in a gas engine the gas is first thoroughly washed and freed of all solid particles.

(To be continued.)

Continental Notes.

IN the *Zeitschrift für Chemische Apparatenkunde* for August 1 there appears a description of a compound centrifugal pump which will give a sufficiently high pressure to deliver feed-water into a steam boiler. This is achieved by having a series of centrifugal pumps all mounted on one axis, and connected up in such a way that each section delivers into the next. It is claimed that the machine possesses an efficiency of 90%, and that under favourable circumstances it is much more economical than the ordinary cylinder pump; it is especially advantageous where electrical power is available at a moderate price.

This issue and the next one contain a paper by M. Parthey on the development of apparatus for the generation of ozone. Descriptions and illustrations are given of those made by Siemens and Halske, Tindal, Marmier, and Otto. The author is of the opinion that as regards technical advantage there is not much to choose between these different types, but those of Siemens and Halske have achieved the greatest practical success, as the difficulties of construction and manipulation have been most completely overcome in them. They all suffer under the disadvantage that the concentration that can be reached is only a very low one; 2 to 3 grammes of ozone per cubic metre of air is the practical limit. For laboratory purposes a greater concentration can of course be attained by the use of oxygen instead of air, but for commercial purposes this would be too expensive. The technical application of ozone has only proceeded very slowly, and the early expectations have not been realised. It was discovered long ago that ozone has a strong germicidal action, and the researches of the Imperial German Department of Public Health demonstrated that the bacteria of diseases such as cholera and typhus are killed by it with absolute certainty when suspended in water. The general opinion now is that the breathing of air containing disease germs is not very dangerous, whereas the drinking of contaminated water is often fatal. Hence it is no longer the custom to attempt to destroy the germs in the air of hospital wards, for instance, whereas the treatment of drinking water with ozone has been applied technically. At Paderborn there is an installation erected by Siemens and Halske, which has been in operation for about five years, for the treatment of a supply from a stream which is not free from contamination. The plant consists of a direct-current machine, an alternating current machine, a fan, nine ozone generators, and the sterilisers. The ozone generators are placed in a dark room in order that it may be seen by the luminosity whether they are working properly. The ozonised air contains 1.7 to 2.2 grammes per cubic foot, and is brought into intimate contact with the water, which flows down a tower filled with coarse gravel. The water is thus completely sterilised, and the taste and smell are improved. In order to get rid of the odour of the ozone, the water is afterwards caused to flow over cascades. The application to other technical purposes has not been so successful, and this is due to the fact that ozone is comparatively expensive, while the same effects can be produced with cheaper materials. Such applications are the bleaching of yarns, the thickening of linseed oil in the manufacture of linoleum, and the bleaching of flour. The odour of the ozone, moreover, is objectionable, especially in the case of the flour. For the treatment of dark oils some success has, however, been attained. In general it may be stated that ozone can only be applied commercially where it is required to remove small quantities of impurities that cannot be attacked by ordinary chemical reagents.

The issues for August and September also contain a paper by A. Dosch on the control of the burning process in boiler furnaces. In order to know with certainty whether the combustion is proceeding satisfactorily in all respects it is necessary to have means for determining the draft or low pressure, which draws the air through the fuel and the combustion gases through the flues, also the temperature either in the firebox or the gas channels, or, best of all, of the gases at the end of the furnace, where the combustion is complete. Finally, it is necessary to ascertain the composition of the flue gases. As regards the first of these items, it is not sufficient to determine the pressure at one point only; what is required is the pressure at two points, such as the damper and the firebox, or the pressure at one of them and the difference of pressure between this and some other point. In the paper a number of ingenious appliances are described for this purpose. Some of them are provided with automatic registering apparatus. The temperature at the point where combustion is complete does not exceed 500° C., and is usually not more than half of this value, consequently it can be measured by means of a mercury thermometer, and no special pyrometers are required. For the determination of the composition of the gases the weight of the gas gives a ready criterion, as its variations are caused almost entirely by differences in the percentage of carbon dioxide. For the determination of the specific gravity of the gases, use may be made of a very simple instrument, consisting of a vertical tube, to the lower end of which a sensitive manometer is connected. By means of a pump the gases are drawn out of the flue and caused to ascend this tube. The gases, being heavier than the outside air, produce a pressure at the base of the long vertical tube, and the measurement of this pressure affords a criterion of the composition of the gas, and consequently of the nature of the combustion process.

POST OFFICE STATISTICS.—The increase in the volume of the Post Office business during the year 1906-7 was considerable, as the following figures, from the report of the Postmaster-General, show. The number of postal packets delivered in the United Kingdom during 1906-7 was 4,862,920,000, an increase of 3.8% over the preceding year. The average number of letters for each person in the Kingdom was 111.1. A striking feature of the report is the enormous number of undelivered packets, either unaddressed or articles found loose. These amounted to 29,766,394, and contained in cash, notes, cheques, etc., the total sum of £714,461. 12s. The number of parcels sent to and received from places abroad during the year was as follows:—Despatched, 2,575,891; received, 1,471,785. The combined total number of outward and homeward parcels shows a net increase over that of the previous year amounting to 142,638, or about 3½%. The total number of foreign and colonial parcels insured, namely 317,255, as against 303,946 in the previous year, shows an increase of about 4½%. According to the Board of Trade returns the value of the goods exported and imported by parcel post during 1906-7 was:—Exports, £4,638,917.; imports, £1,535,661.; total, £6,174,578. The increase in 1906-7 as compared with 1905-6 was:—Exports, £463,256.; imports, £5,293.; total, £468,549. The number of postal orders issued during the year was 102,247,000, and their value amounted to £40,878,000. These figures show increases of 5.1 and 5.4% respectively over those for 1905-6. The value of the postage stamps affixed was £218,000. The commission on these orders yielded the sum of £415,041., or £13,821. less than in the previous year. The decrease is due to the reductions in poundage which came into force in July, 1906.

THE CHINESE CAMPHOR INDUSTRY.

A BRITISH *Consular Report* states that the quantity of camphor exported from Foochow increased in 1906 to a degree at once noticeable and unprecedented. The 4,805 cwts. of 1905 rose to 13,535 cwts. in 1906. The report goes on, however, to observe that to those interested in the trade this spasmodic expansion is like the dying flicker of a candle, and that the exploitation of camphor in Fukien is an industry which will shortly perish of inanition.

The camphor industry is handicapped by inherent difficulties of manufacture—difficulties, moreover, for which it appears impossible to find a remedy. Similar intractibility has long puzzled the manufacturers of rhea, and the ingenuity of inventors has been stimulated by the offer of large rewards by the Government to any genius who should devise a satisfactory method of treating that fibre. Inventors might, with advantage, turn their attention to the camphor problem. Most people know that the only way in which camphor can be extracted from the tree is by a process that might be termed "destructive distillation." To obtain the drug the tree must be felled and its timber boiled. The camphor can only be extracted by boiling, therefore the tree must die after the extraction has been made. Chinese camphor comes chiefly from Formosa, and forms the only other source of supply for European markets. It is a product of *Cinnamomum Camphora*, one of the *Lauraceæ*, and constitutes the bulk of the world's supply. Since Formosa passed out of the hands of China, the Japanese have expended much thought and pains on the cultivation, and have made many experiments with a view to ascertaining whether it is possible to obtain the drug without destroying the tree. At one time it was hoped that camphor might be distilled in sufficient quantity from the twigs and leaves without destruction of the trunk, but this hope has been proved fallacious, and those investigating the question have reluctantly had to conclude that the only possible method of preserving the species is to plant fresh trees in place of those sacrificed. To make this device successful, however, half-a-century's patience is required, for *Cinnamomum Camphora* is a tree of slow growth, and is not commercially productive till it has attained the age of forty years. The cultivation of the camphor tree is, therefore, a business in which it is hopeless to look for quick returns for one's outlay. It is several years since the Fukien authorities had their attention turned to camphor as a promising source of provincial revenue. Since this discovery they have made repeated attempts to create a Government monopoly of its production. But every such attempt has been vigorously resisted by the treaty Powers.

It is evident from the customs returns that the manufacture of camphor is being prosecuted energetically in the province, which is equivalent to saying that camphor trees are being increasingly destroyed. As the number of these trees in this and the neighbouring province of Chékiang is strictly limited, the extirpation of *Cinnamomum Camphora* in Fukien is only a question of time, and a very short time too. It is true that the provincial Government is alive to the advisability of planting at least one sapling for every adult tree cut down; indeed, they require that renovation shall take place at the rate of five for one. But, as before mentioned, the camphor tree takes a long time to arrive at maturity, and the authorities are legislating for a very distant future. Besides, it is said of the existing trees that a considerable number do not produce camphor. Some theorists assert that, like the cocoanut palm, *Cinnamomum Camphora* grows to perfection only close to the sea. Others, that camphor trees are male and female, and that crystals of the desired quality are found in the male only. This theory is, however, scientifically inexact, since the flower of *Cinnamomum* is polygamous. However this may be, it is obvious that the jump from 4,482 cwts. in 1905 to 13,535 cwts. in 1906 bodes ill for the survival of the industry, and that the days when camphor will continue to form one of the Foochow exports are numbered.

For this regrettable state of things there appears to be only one possible remedy, and that is systematic reafforestation on a definite plan. Let the authorities utilise what stock in the way of adult camphor trees they have by cutting trees down and boiling the wood, so as to make as much money as they can. In any case that is probably what they will do, whatever advice may be tendered to them, and fortunately the survival of old trees is not essential as an encouragement to their youthful successors. But the Government should simultaneously establish at certain suitable points camphor tree reservations, nurseries of young trees, which are to be strictly protected from the woodman's axe for, say, 50 years. By some such means Fukien might again become a camphor-producing province towards the end of the century. It would also be useful to ascertain whether it is a fact that certain camphor trees produce the drug and others of an apparently kindred species do not, and what the reason of the difference is. For, of course, it is essential that the *Cinnamomum* to be cultivated in the proposed nurseries shall be of the right sort. The Chinese cannot distinguish by mere ocular inspection the useful from the useless, and only the experimental boiling of chips enables them to discriminate.

Export of camphor during the past five years :—

Year.	Quantity. Cwts.	Value. £
1902	264	1,460
1903	1,362	8,287
1904	1,421	10,084
1905	4,805	43,039
1906	13,535	185,852

Prices ruled from 127 to 166 dol. per picul (first cost), but have been very irregular owing to Chinese shippers competing with each other. Complaints have been made of the damp nature of much of the cargo, which is due to hasty shipment, the Chinese not having facilities or inclination to dry the cargo. Most of the camphor goes to Hong-Kong for distribution, chiefly for London, the Continent and India. The season saw a large increase of shipments direct to London.

The export of camphor oil (shown below) began in 1903, and has been steadily increasing in volume :—

Year.	Quantity. Cwts.	Value. £
1903	624	993
1904	744	1,380
1905	349	600
1906	3,796	8,344

Correspondence.

*** *We do not hold ourselves responsible for the opinions expressed by our correspondents.*

CASEIN.

(*To the Editor of the Chemical Trade Journal.*)

Sir,—As subscribers of your *Journal* we find an inquiry respecting Casein in the columns of your issue for August 31st, and as we are large dealers in this article we should feel obliged if you would hand over our address to "Liverpool Inquirer."

Yours truly,

Brüggehaus, Hamburg, 16th September, 1907. LEHMANN AND VOSS.

Answers to Correspondents.

We cannot undertake to reply to correspondents through the post. Those of our readers who have addressed queries to us should look in this column for a reply.

W. J.—Corrected M.S. duly received.

C. W. C.—Matter and block duly to hand.

W. G. W.—M.S. duly to hand. We are considering this.

J. J. G. AND S.—Thanks for letter. We are testing the apparatus.

M. N.—Letter duly received, and we are glad to note the explanation.

G. L. Co.—We note contents of your letter of the 17th inst. We have this article in hand.

J. H. F. AND Co.—We are looking into this matter, and will write you in the course of a post or two.

W. H. B. AND Co.—We shall publish a report of this Exhibition, and will include the plant you mention.

C. F. A. F.—You will find two letters on this subject in our last issue. We think these will give you the information desired.

D. G. U. S.-S.-A. V. R.—We are referring to the source of the paragraph, and, if possible, will send you a copy of the paper.

CHANGE OF ADDRESS.—From a notice on another page, our North-country readers and clients will see that from Monday next, the 23rd inst., our Manchester address will be Barton House, 66, Deansgate.

Analytical Notes.

THE INFLUENCE OF IRON IN COPPER ELECTROLYSIS.

By E. L. Larison.*

The metal most frequently associated with copper is iron, and the separation of these two is the commonest which the analyst must make. Qualitatively the separation presents no difficulties by electrolysis; that is, in depositing copper by an electric current there is no danger of contamination by iron, and the separation is complete. An examination and comparison of current densities, voltages, and time required for the deposition of a given quantity of copper in the presence of varying amounts of iron, shows that quantitatively its influence is a considerable matter.

The following results show the retardation of varying amounts of iron. The materials used were $CuSO_4—5H_2O$ and $FeSO_4—7H_2O$. The iron was oxidised by nitric acid in each case, and after neutralisation with NH_4OH, 2 c.c. each nitric and sulphuric acids were added.

No.	$CuSO_4$ Grammes.	$FeSO_4$ Grammes.	Amp.	V.	Time, Minutes.	Cu, Grammes.
(1)	0.5	..	0 7	3.1-3.5	15	0.0870
(2)	0.5	0.25	0.8	3.3	15	0.0822
(3)	0.5	0 50	0 75-0.8	2.9-3.0	15	0.0766

The following on 1-gramme samples of two grades of matte and a heavy sulphide ore:—

No.	Material.	Fe, per cent.	Cu, per cent.	Amp.	V.	Time, Minutes.
(1)	Matte.	25.23	47 07	1.65	3 0	100
(2)	Matte.	46.38	19.65	1.70	3 2	85
(3)	Ore.	33.43	2.45	1.35	3 5	54

These latter results were obtained with rather high current density and using a stirrer. They show the effect of high iron percentages in practical daily determinations. It is striking to note that in No. 1 0.4707 gramme Cu was deposited in a little less than double the time required for about 1/20 of that amount in No. 3.

It is usual and almost essential to effect decomposition, and solution of copper, by means of nitric acid. The iron present will always exist then as a ferric salt when the solution is put on the battery. The following results, obtained with salts, show quite clearly that it is iron in the ferric state that retards the operation.

No. 1 contained no iron. No. 2 contained iron in the ferrous condition. In No. 3 the iron was oxidised to the ferric state by nitric acid. After making neutral with ammonia, 2 c.c. each nitric and sulphuric acids was added to have conditions the same as in practice. This small amount of nitric acid added to a cold solution of volume 200 c.c. can exercise scarcely any oxidising action.

No.	$CuSO_4$, Grammes.	$FeSO_4$, Grammes.	Amp.	V.	Time, Minutes.
(1)	1	..	1.3	3.5	60
(2)	1	1	1.3	3.1	65
(3)	1	1	1.3	2.9	90

The current apparently must reduce a certain amount of the ferric iron to the ferrous condition before all the copper can be deposited. A solution going on the battery usually contains at the start $CuSO_4$, $(Fe)_2(SO_4)_3$, H_2O, H_2SO_4, HNO_3 and possibly small amounts of other salts which can usually be neglected.

At the cathode copper is deposited and hydrogen set free. The solution is very ready to use hydrogen, however, and few bubbles of it can be seen. It probably reacts mostly with the ferric sulphate and slightly with the nitric acid. Ferric sulphate is reduced to ferrous

$$Fe_2(SO_4)_3 + 2H = 2FeSO_4 + H_2SO_4.$$

Nitric acid is reduced to ammonia, which is immediately neutralised by the excess of nitric and sulphuric acids.

$$HNO_3 + 8H = NH_4OH + 2H_2O.$$

In time this reaction may proceed so far as to make the solution alkaline. Hydrogen bubbles also appear in increasing numbers as the reduction proceeds.

* In the *Engineering and Mining Journal* (New York).

At the anode, in a solution like the above, oxygen is given off freely from the start. It is due both to a decomposition of water by the current, and by the SO_4 ions set free in the breaking up of $CuSO_4$. Very often the anode is slightly covered with manganese or lead oxides.

The process of electrolysis exercises in the main a reducing influence on an electrolyte such as the above. Further reduction, and probably the retardation of the deposition of copper, comes about through some such reaction as the following:

$$Cu + Fe_2(SO_4)_3 = CuSO_4 \times 2FeSO_4.$$

That is, copper already deposited or on the point of being deposited is attacked by the ferric sulphate and dissolved, thereby also reducing the ferric to ferrous sulphate. When the process has gone on for a time, the electrolyte becomes so dilute with respect to the ferric sulphate that the last of the copper is able to keep its place upon the cathode. This accounts for the difficulty of, and comparatively great time necessary for, the removal of the last few milligrams of copper from a solution high in iron. When using a stirrer and high currents, a very small reduction in the current density is quickly followed by the re-solution of much of the deposited copper. It seems as if the copper is able to keep its place on the cathode only with a certain electrical or reducing tension.

A frequent occurrence with solutions high in iron is the formation of a "brown ring" similar to the characteristic test for nitric acid and nitrates. This indicates re-oxidation of the ferrous salt by the nitric acid, and usually means a slow deposition of copper. If the solution be stirred after this brown ring appears, a large part of the deposited copper will be quickly dissolved.

In order to determine the extent of reduction, whether there is any uniformity about it, and the effect of stirring, the following figures were obtained. The solution in each case contained 2 c.c. each nitric and sulphuric acids, and the volume was 200 c.c. The amount of iron reduced was determined by titration with permanganate, after all copper was deposited.

Solution Stirred.

No.	Material.	Fe, per cent.	Fe, Red.	Fe, Rem.	Amp.	V.	Time, Minutes.
(1)	Matte.	25.23	19 39	5.84	1.65	3.0	100
(2)	Matte.	46.38	40 13	6.25	1.70	3 2	85
(3)	Ore.	33.43	26.62	6.81	1.35	3.5	54
(4)	0.2g. Fe.		0 15g.	0.05g.	0 1	2.6	100

Solution Stationary.

No.	Material.	Fe, per cent.	Fe, Red.	Fe, Rem.	Amp.	V.	Time.
(1)	Matte.	25.23	16.10	9 13	0 3	2.4	13 hr.
(2)	Matte.	46.38	37.5	8 88	0.3	2.5	10 45m.
(3)	Ore.	33.43	23.49	9.94	0.3	2 5	5 45
(4)	0.2g Fe.		0.057g	0.113g	0.1	2.5	100

In each of these cases only a small part of the iron is not reduced. There seems to be a fairly uniform amount remaining too, at least, in each group taken separately. In the stirred solutions, from 5 to 6% of the iron remains in the ferric state, while if they are left stationary from 9 to 10% remains. This reduction cannot be considered as merely incidental, because of the very obvious retardation of copper deposition, also because of the uniformity of the reduction. It is to be expected that it would have to proceed farther in the stirred solution for the reason that a solvent is always more effective if circulated.

Circulation of the solution not only allows the use of higher current densities and thereby more rapid work, but it gives the current greater efficiency, as the above results show. Less ampere-hours are necessary to deposit a given amount of copper if a solution is stirred than if it is stationary. This is due not only to the fact that the solution is kept uniform and the copper deposits more rapidly, but also the reducing effect on the iron is much greater, and consequently the dissolving power of the solution is decreased much sooner. The retardation when using a stirrer, while distinctly noticeable, is not so important as when the solution is stationary. A very rapid method of reducing iron before applying the current would save time. The ordinary methods of reduction all have objections or take too much time to be of advantage.

The influences of iron in copper electrolysis may be summed up as follows:—

(1.) High percentages of iron in the ferric condition materially retard copper deposition. Ferrous salts have little or no effect.

(2.) The effect of the electric current in the usual solution is to reduce ferric salts to ferrous. This reduction must proceed

Digitized by Google

to a certain point before all the copper will remain on the cathode. This point is about the same whatever be the iron and copper percentages, but it varies some as the solution is circulated or stationary.

(3.) Rapid circulation of the solution by a stirrer permits the use of high current densities without sponging, thereby making deposition faster. The current also is more efficient for both depositing copper and reducing iron.

THE VOLUMETRIC ESTIMATION OF ZINC.

By A. R. THORNEWELL.

The disadvantages of the standard "sodium sulphide" methods for the volumetric determination of zinc lie chiefly in their uncertain end-reactions; in the "ferrocyanide" method, temperature and the quantity of acid present make the end, under certain conditions especially, variable.

In the method suggested herein, the end-reaction is quite sharp, and zinc is not used in standardising the solutions employed. Its principal disadvantage is having to wait for the zinc sulphide precipitate to settle. The method is based on the following reactions:—

(1.) $2NaOH + H_2S = Na_2S + 2H_2O$.
(2.) $ZnSO_4 + Na_2S = ZnS + Na_2SO_4$.
(3.) $Na_2S + H_2SO_4 = Na_2SO_4 + H_2S$.

Normal soda solution is saturated with sulphuretted hydrogen, the zinc precipitated with this solution, and the excess of soda titrated. It can be looked upon as NaOH and not Na_2S, as the sulphide is only a means to an end, and acts under the condition of the experiment as an alkali.

Method.

Sufficient of the sample is taken to produce 200 c.c. of solution containing about 0.00327 gramme Zn per c.c. The solution must be neutral and free from other bodies precipitable as sulphides under similar conditions. Now take 25 c.c. of normal soda, or any other quantity that will give an excess, saturate with sulphuretted hydrogen, and add to the zinc solution. Shake, make up to 250 c.c. with water when cold. Let this stand in a warm place for the pricipitate to settle, pour off the supernatant liquor into a Squibb's separator preferably on account of the wide hole in the tap; allow to stand, draw off the precipitate by the tap, cool, and pour off samples for titration into 25 c.c. measuring flasks. As many samples as will be required should be poured off at once; otherwise there is great danger of stirring up any residual precipitate. This is the most troublesome part of the operation, but by pursuing this practice it is easily overcome. The samples are now turned into conical flasks, and 25 c.c. decinormal sulphuric acid run into each. They are now boiled free from sulphuretted hydrogen, cooled, and the excess of acid titrated with decinormal soda, using methyl orange as the indicator.

Every 25 c.c. of sample taken contains 2.5 c.c. normal NaOH, and equals 25 c.c. decinormal NaOH. The excess of decinormal H_2SO_4 deducted from the total H_2SO_4 used, gives the amount of decinormal H_2SO_4 required to neutralise the excess of NaOH originally added; therefore this H_2SO_4 as c.c. of decinormal deducted from 25 gives the amount of normal NaOH stated as decinormal used in precipitating the zinc in 25 c.c. of solution, and equals one-tenth of the sample taken. One c.c. decinormal NaOH = 0.00327 gramme zinc. The calculation may also be stated as follows:—

$$x = (a + b - c) \times 0.0327$$

where x = grammes of Zn in amount of total sample taken;
a = c.c. N/1 NaOH used;
b = c.c. N/10 NaOH used in titrating excess of N/10 H_2SO_4 used;
c = c.c. N/10 H_2SO_4 used.

Example: a = 28.1 c.c. b = 16.69 c.c. c = 24.875 c.c.
$x = 28.1 + 16.69 - 24.875 \times 0.327 = 0.6512$ gramme of zinc.

The Chemist and Druggist.

PRESERVATIVES IN MILK.—On Wednesday week, at Yarmouth, several milk dealers were fined 40s. and costs for selling adulterated milk. Two others were ordered to pay the full penalty, £20, and costs, or undergo two months' imprisonment. Samples of the milk sold by these two dairymen contained a large quantity of formaldehyde, which the Medical Officer of Health described as a most irritant poison and the worst of all preservatives.

IMPORTS OF METALS AND MINERALS.

THE following returns, which are taken from the foreign and colonial statistics of the United Kingdom, give the amount and value of metals and minerals imported during the month of August, 1907, as compared with August, 1906:—

THE LATE DR. DUPRÉ.

THE current number of the *Analyst* contains some interesting notes on the career of the late Dr. August Dupré, F.R.S., from which we extract the following.

When, in 1874, the shortcomings of the Adulteration Act of 1872 led to the appointment of a Parliamentary Committee, the few analysts that held office under that Act felt that the time had come to guard their and the public interests by combining together and forming a society. Food analysis had until then to some extent been in the hands of amateurs, devoid of adequate training and knowledge, and complaints regarding the ability and mode of procedure of Public Analysts were not unknown. Dupré, who at that time had previously been engaged in the study of the chemistry of wine (papers of his having been published in the *Chemical Society's Journal* of 1867 on the acid and sugar present in grapes during the progress of ripening, on the estimation of compound ethers in wine, on the effects produced by the addition of plaster of Paris to must, etc.), and who had just published, in conjunction with Dr. Thudichum, a most comprehensive book on wine, and was already at that time a prominent and honoured member of our profession, was induced to join in the movement, to which the weight of his name and position greatly helped to give solidity and importance. The early days of the Society of Public Analysts were full of stress and dissension, and it was greatly due to Dupré that the young society was kept alive.

He contributed a stream of papers to its proceedings which, like a great deal of his other work, have in time rather increased in importance than—as is the natural fate of a great deal of chemical work—gradually to lose in significance. Thus, his paper on the "Examination of Whisky and other Spirits for Fusel Oil," with which No. 1 of vol. i. of the *Analyst* opened, showed that amyl-alcohol could be quantitatively oxidised to valerianic acid and thus estimated, led the way to all subsequent work on this matter. His contributions towards the analysis of butter-fat, in the same volume of the *Analyst*, laid the foundation of the alkalimetric estimation of glycerides, as he had previously laid that of other esters in a similar way. We owe to him the method for the estimation of alum in flour and bread, which is still in use. He was foremost in giving the now orthodox modes of water analysis their present form, and contributed to the analytical methods of the examination of alkaloidal and other drugs. In conjunction with Dr. Bence-Jones, he was the first to observe the formation of alkaloidal substances by the decomposition of animal matters. The bodies which we now call "ptomaines" he termed "animal quinine." With Dr. Odling, he discovered the almost universal presence of copper in vegetable and animal materials.

His scientific mode of thought, openness of character, and directness of speech, as well as his fine physique, made him the centre for many years of the earlier meetings of the Society of Public Analysts. As its President in 1877 and 1878, he was never tired in stimulating the younger members towards scientific exertions, and many of the papers which were contributed were directly due to his suggestions.

When the Institute of Chemistry was founded, against the opposition of some of the members of the Society of Public Analysts, Dupré threw his energy into the movement, and he took an active part in the often heated discussions from which the present beneficent policy of the Institute ultimately emerged. Here and at the Chemical Society's meetings he was for many years a regular attendant, and whenever he spoke he was impressive by knowledge and common-sense. For about ten years his visits at meetings were rare, a slight paralytic stroke rendering speech difficult for him. During the last two years before his death he was ailing, and his final illness was long and painful.

He was born in Mainz on September 6, 1835, the second son of J. F. Dupré, his mother dying a few days after his birth. His father, who was a descendant of a Huguenot family, came to England in 1843, and lived at Warrington until 1845, when he returned to Germany, settling at Giessen. There August and his brother Fritz went to school till 1850, and thence to the technical school at Darmstadt until 1852. Both brothers studied chemistry at Giessen under Liebig and Will, and at Heidelberg under Bunsen and Kirchhof. They came to London in 1855, after A. Dupré had taken his Ph.D. degree in Heidelberg. He became assistant to Dr. Odling, who then had a laboratory in Kennington, and thence went to Guy's Hospital. In 1863 he succeeded his brother as lecturer of chemistry to the Westminster Hospital Medical School; this post he resigned about ten years ago. Since then he practised as consultant at Howick Place, Victoria-Street, Westminster, his two sons assisting him. In 1871 he was appointed Chemical Referee to the Medical Department of the Local Government Board; in 1873 Public Analyst for Westminster, and also Chemical Adviser to the Explosives Department of the Home Office; in 1888 a member of the War Office Committee on Explosives, and in 1900 a member of the Ordnance Research Board.

A great deal of his energy was spent in connection with his appointment to the War Office Committee. He carried out innumerable investigations on various forms of explosives, and to him is almost solely due the "heat test," which of late has been much discussed and criticised, but which was undoubtedly instrumental in raising the standard of purity and stability of nitro-explosives throughout the world, and which has rendered their manufacture extraordinarily safe. Thousands of new mixtures of explosive substances passed through his hands, and none were licensed for manufacture or import unless he had satisfied himself that they were of sufficient stability and safety. The annual reports of H.M. Inspectors of Explosives bear lasting testimony to the immense labour, knowledge, and care which he brought to bear upon this part of his life's work.

During the Fenian outrages in 1882-83, explosions being caused or attempted in many parts of London and the country, he rendered enormous public service in their investigation.

The Government seemed to be duly grateful to Dr. Dupré, as appears from the report of Parliamentary proceedings in the *Times*, April 17, 1883: "Mr. Salt asked the Home Secretary if he would take into consideration whether some special and adequate acknowledgment could be given to the officers who were engaged in the discovery or removal of the dynamite and other explosive materials recently captured." Sir William Harcourt said: "I do not wish to lose any opportunity of bearing my testimony to the courage and skill exhibited by Major Majendie, the Inspector of Explosives; by Dr. Dupré, the eminent chemist; and by other gentlemen to whom the hon. member has alluded; but I would ask that the House, feeling that the Government are not insensible of these things, should leave the matter to the executive." It is a matter not redounding to the honour of the executive that they utterly forgot this promise, and that the high and numerous public services of Dupré to the State were left unrewarded. The inborn modesty, the utter absence of the quality known as "push," his almost childlike unworldliness, left him unnoticed where so many less noble natures were exalted.

Dupré was frequently consulted by the Treasury, the Board of Trade, the Wreck Commissioners Court, and the late Metropolitan Board of Works. He made extensive investigations into the condition of the River Thames, devised in this connection an admirable method for the determination of dissolved oxygen in water, advised on sewage treatment, and to him is due the inception of the bacterial treatment of sewage which is about to overthrow all previous empirical modes of sewage disposal. In 1885 he reported that "the destruction of organic matters discharged into the river in the sewage is, practically, wholly accomplished by minute organisms. These organisms, however, can only do their work in the presence of oxygen, and the more of that you supply, the more rapid the destruction. If the river could only be kept aerated, no harm would result from the introduction of the sewage."

He was made a Fellow of the Royal Society in 1875. His contributions to scientific literature, as contained in the *Philosophical Transactions*, *Proceedings of the Royal Society*, *The Journal of the Chemical Society*, *The Analyst*, and the *Journal of the Society of Chemical Industry*, would form a very long list, but almost the major part of his work is recorded in Blue-books and Government Inspectors' Reports, which are not ordinarily before the public eye, and whence, it is to be hoped, they may some time be collected by loving hands.

Obituary.—The death took place at Swanage, on Saturday last, of *Professor L. F. Vernon Harcourt*, the well-known civil engineer. Professor Harcourt was educated at Harrow and Balliol College, Oxford, where he took a first-class in mathematics and in natural science. From 1866 to 1870 he was engaged as resident engineer on the South-west India Dock works. In 1882 he became professor of civil engineering at University College, London. He acted as British member of the jury for civil engineering at the Paris Exhibition of 1900 and at the St. Louis Exhibition of 1904. He was the author of a number of papers and books on civil engineering, and was regarded as an authority on canals.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

These abstracts are specially prepared for the Chemical Trade Journal, and ALL RIGHTS *of publication are* RESERVED. *This is the earliest series of abstracts of Chemical and allied patents accessible to the public.*

Improvements Relating to the Manufacture of Explosives. C. Duttenhofer, Bergedorf, near Hamburg, Germany. British Patent, 19,408. August 30, 1906.

This invention has for its object improvements in the process described in Specification No. 24,782 of 1904. In this specification is described a process for avoiding muzzle flames when firing nitrocellulose-nitroglycerine powder, by the addition of small quantities of neutral substances such as vaseline or the like and alkali bicarbonate to these powders. The inventor has found, however that salts readily soluble in water, such as the alkali bicarbonates mentioned in the prior specification when stored in humid places, casemates, ships' holds and also in the tropics, have proved to be very hygroscopic, and owing to the absorption of water the powders alter somewhat. It therefore became necessary to endeavour to find bodies which are less hygroscopic, and which, if possible, are partly soluble in the solvents such as acetone, etc., used in the manufacture of the powder, and this in order that they may become better distributed in the powder. The inventor has found that very precise quantities of the salts of the dibasic organic acids in combination with oils, fats and resins are especially adapted for eliminating the defect referred to above. In addition to this, this combined employment of the substances referred to, especially in combination with resins such as colophony, for example, presents further advantages with reference to the storability of the powder and as regards moulding and drying. Thus, for example, a nitroglycerine-nitrocellulose powder becomes specially tough or viscous by the combined addition of colophony or other appropriate resin with the salts mentioned, and accordingly the specific weight of the powder is increased. In addition to this it is possible to add this substance to almost any desired quantity to a powder with highly nitrated nitrocellulose. The inventor is aware that it has already been proposed to add to nitro-glycerine-nitro-cellulose explosives such substances as olive oil and alkaline metals or castor oil, magnesium carbonate and cotton pulp, combined with relatively large quantities (4% and over) of salts such as the acetates, borates, citrates, oxalates and tartrates, but he has proved by exhaustive experiments that such additions do not reduce the amount of muzzle flame, but considerably augment it, in addition to diminishing the ballistic efficiency of the powder.

The invention therefore consists in the improved means for preventing muzzle flaming with the said powders by the combined addition of small quantities of indifferent substances such as oils, fats, resins and the like, with precise quantities (1-2%) of salts of the dibasic organic acids, such as tartaric acid, lactic acid, oxalic acid, malic acid, pyro-mucic acid, salicylic acid and the like.

Improvements in the Application of the Electric Arc for Producing Reactions in a Gaseous Mass and in Apparatus therefor. A. A. Naville, P. A. Guye, and C. E. Guye, all of 3 Chemin des Cottages, Geneva, Switzerland. British Patent, 21,338. September 26, 1906.

The improvement consists in causing an electric arc to play within the gaseous mass, this arc being subjected to the action of a rotary field. When the arc is produced by a continuous current the rotary field sets it in continuous rotation; when the arc is produced by an alternating current the effect of the rotary field is to set it in oscillatory rotation. Electrodes of many types may be used, the appearance of the rotating arc depending on the type. The rotary field may be produced in any known manner; in a suitable form of apparatus the rotary field is produced by two systems of rectangular electro-magnets energised by two-phase currents. A type of furnace for this invention comprises a narrow chamber of insulating and refractory material containing as one electrode a disc having a projecting brim, preferably extending towards the other electrode, or a cone, and as the other electrode a tube through which the gases may pass. With an alternating current the periodicity of the arc current may be the same as, or different from, that of the rotary field. In the former case the arc will oscillate; in the latter case an oscillatory rotation will be produced which will vary in speed accordingly as the difference between the two periodicities is greater or less.

Improvements in the Manufacture of Barium Cyanide. J. Y. Johnson, 47, Lincoln's Inn Fields, London (communicated by the Badische Anilin and Soda Fabrik, Ludwigshafen-on-Rhine, Germany). British Patent, 22,039. October 5, 1906.

The patentee observes that although Margueritte and Sourdeval's process for the production of barium cyanide by heating together carbonaceous material and barium oxide, or barium carbonate, in the presence of nitrogen gas, was discovered in the year 1860 it has not hitherto been capable of being carried out on a commercial scale owing to the small yield of barium cyanide obtained. Experiments have shown that high temperatures are advisable during the reaction in order to cause as much nitrogen as possible to enter into combination, but the quantity of cyanide formed is not in proportion to the quantity of nitrogen combined, because at high temperatures the barium cyanide tends to split up into barium cyanamide and carbon according to the equation $Ba(CN)_2 = BaCN_2 + C$, and the inventors have discovered that this splitting up increases as the temperature increases, while at lower temperatures the reverse action takes place, barium cyanamide combining with carbon and forming barium cyanide. It would therefore naturally be expected that, during cooling down from the high temperatures employed, the barium cyanamide present would combine with the carbon which separated out at those high temperatures and that the cold product would consist of barium cyanide with little or no
